Comment cette “vision” a-t-elle changé?

Un peu d'histoire

Naissance de la radioastronomie

1933-37: Karl Jansky (USA) :
découverte ondes radio extraterrestres
1943-46: Grote Reber (USA) :
Cartes à 160 et 480 MHz

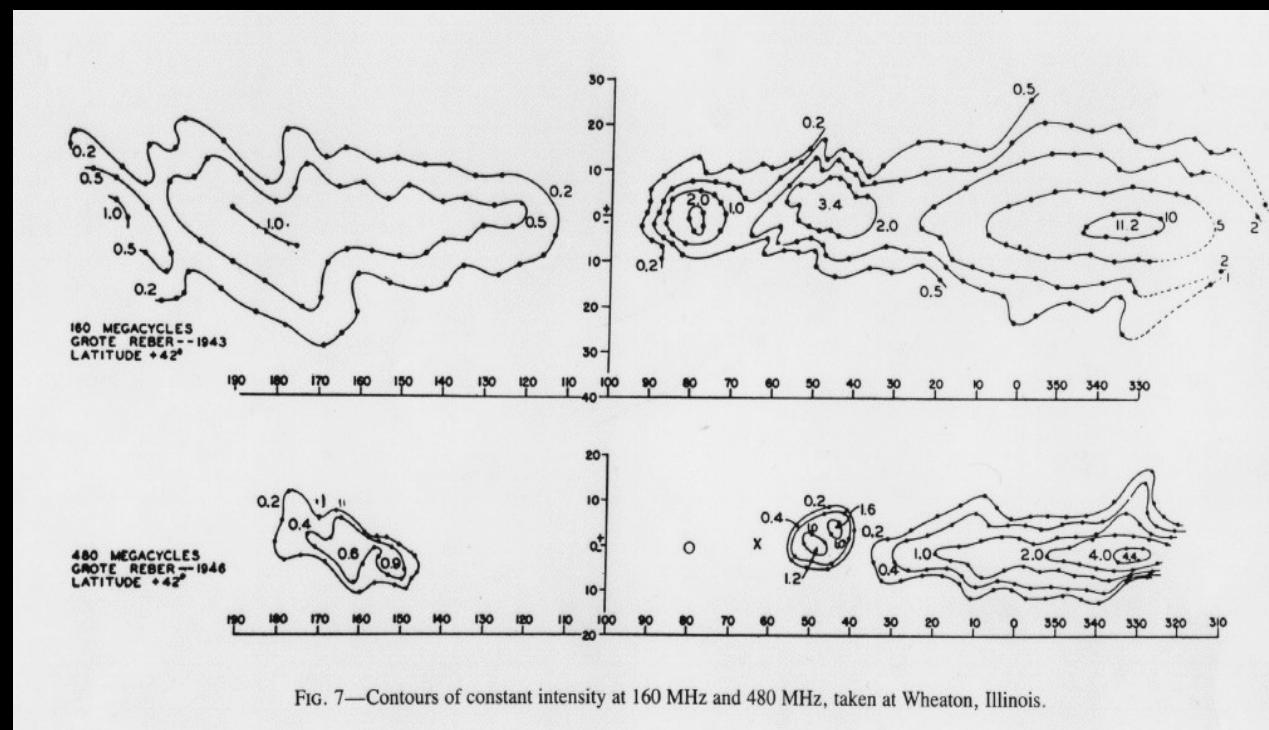

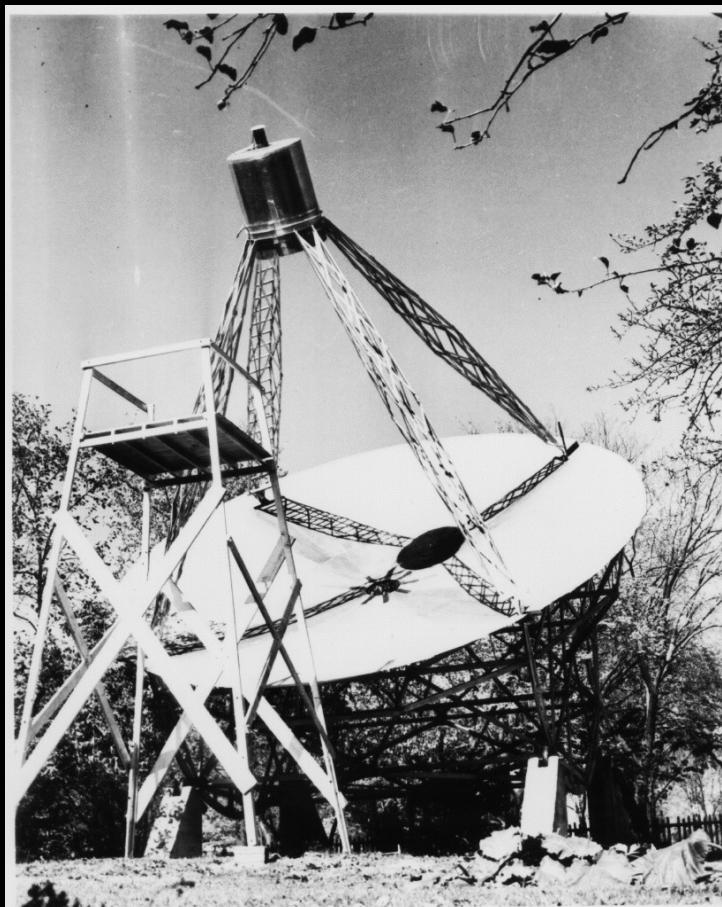

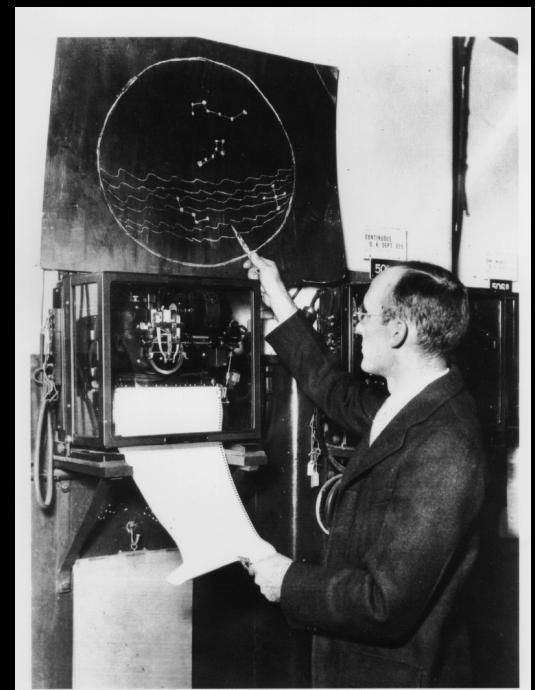

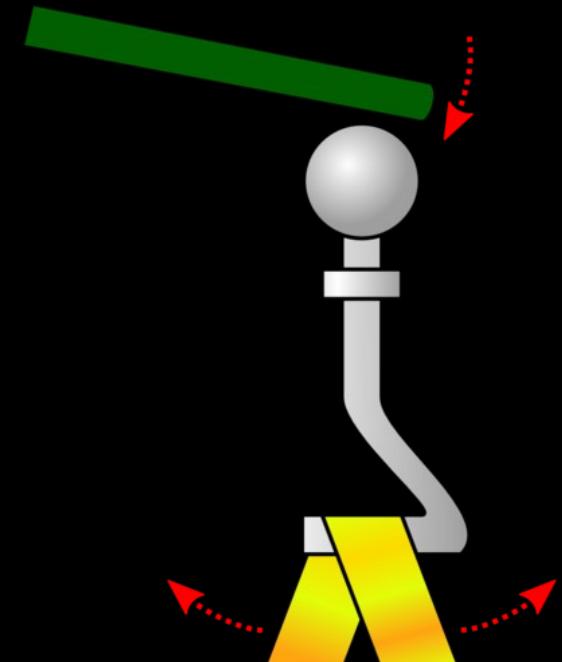

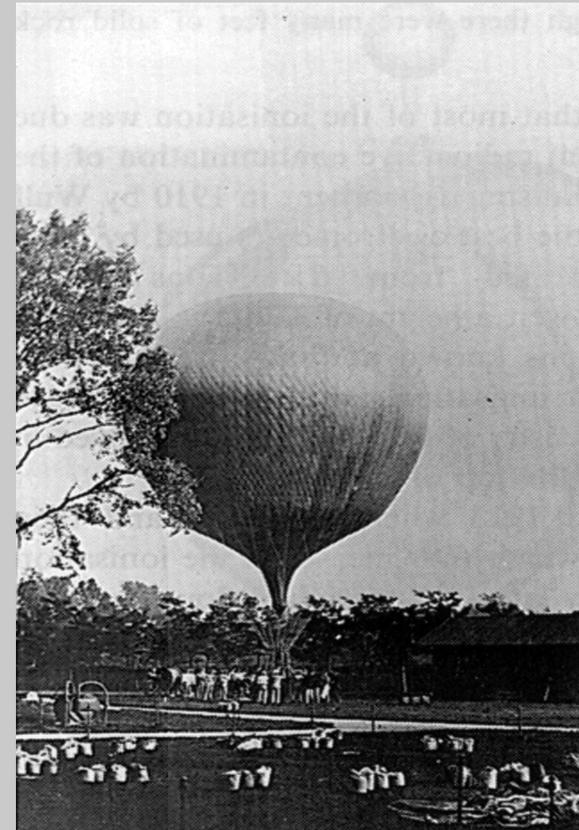

FIG. 7—Contours of constant intensity at 160 MHz and 480 MHz, taken at Wheaton, Illinois.

Rayons cosmiques : découverte

1896: Découverte de la radioactivité Henri Bequerel

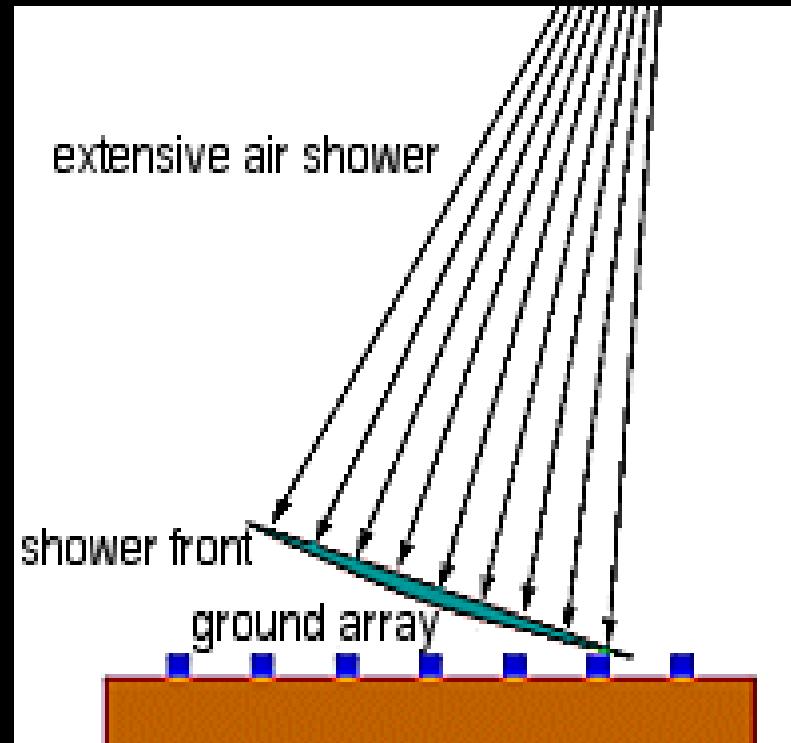

1912-13: Vols héroïques de Victor HESS et Werner Kolholster :
découverte originie extraterrestre des rayonnements ionisants
L'hypothèse admise seulement en 1927

Rayons cosmiques : apogée

1934 Bruno Rossi : Compteurs Geiger

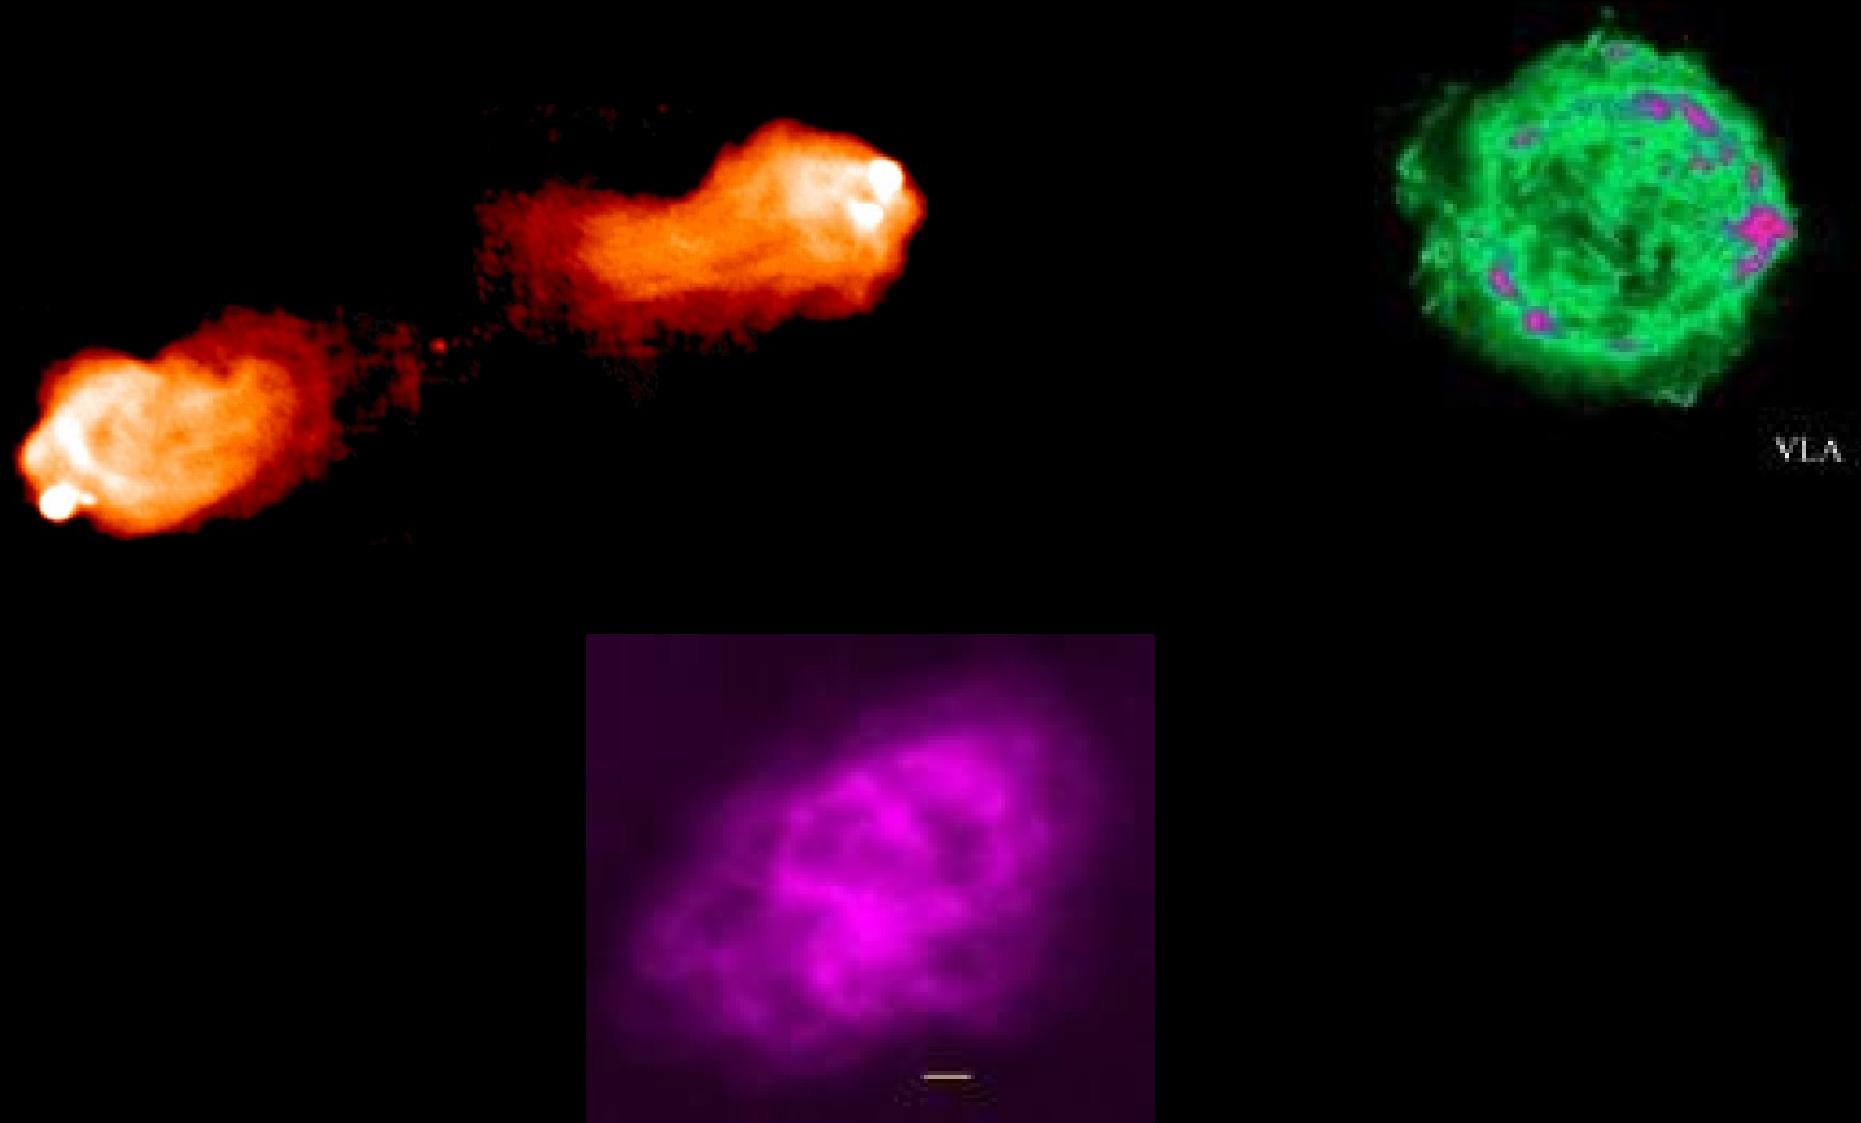

1937-38: Expériences de Pierre Auger : Particules d'énergies 10^{15} eV

Années 1950-54
Pont entre la radioastronomie
et
les rayons cosmiques

La radioastronomie

1946-50: Premières sources discrètes : Cyg A, Cas A, Crabe ...

Rayonnement synchrotron et polarisation

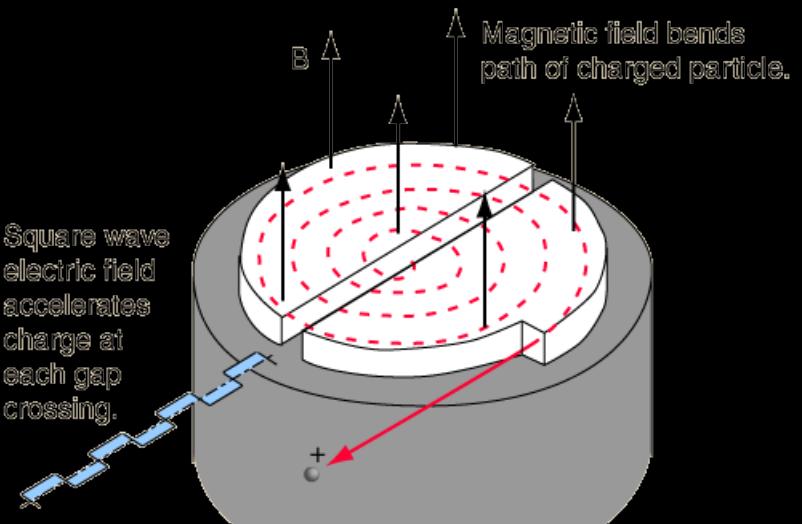

1946: John Blewet: Première observation du rayonnement synchrotron

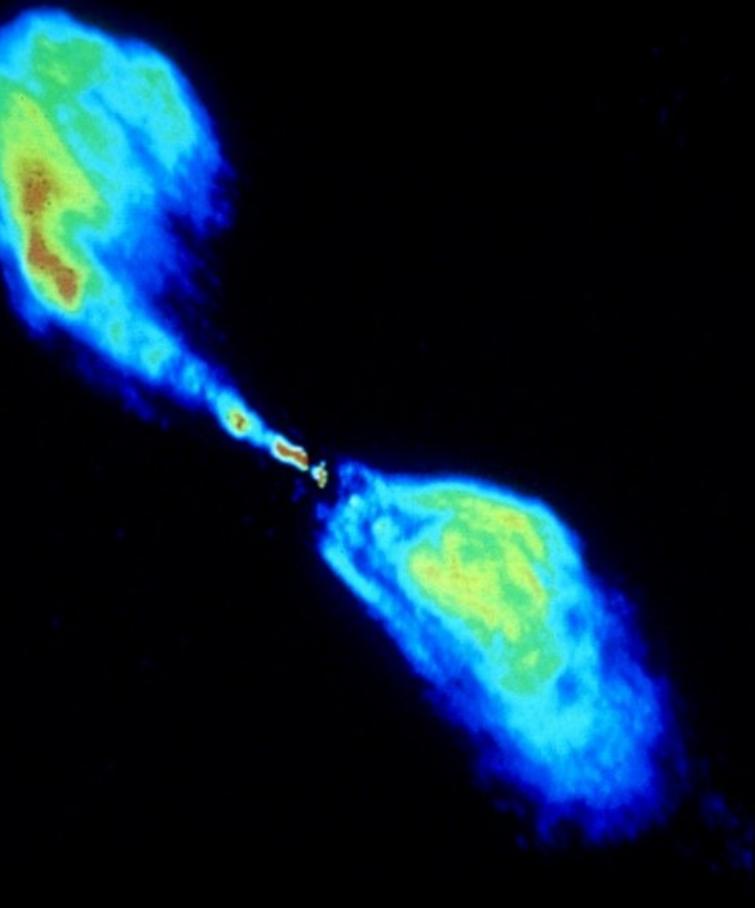

1946-49: Julian Schwinger : calculs théoriques

1950 Karl-Otto Kiepenheuer, puis Guinzburg 1951:
émission diffuse : rayonnement synchrotron

1952: Iosif Shklovskii :
émission optique du Crabe : synchrotron

1954: Victor Dombrovski et Mikhail Vashakidze:
mesure en optique

VLA: 6 cm

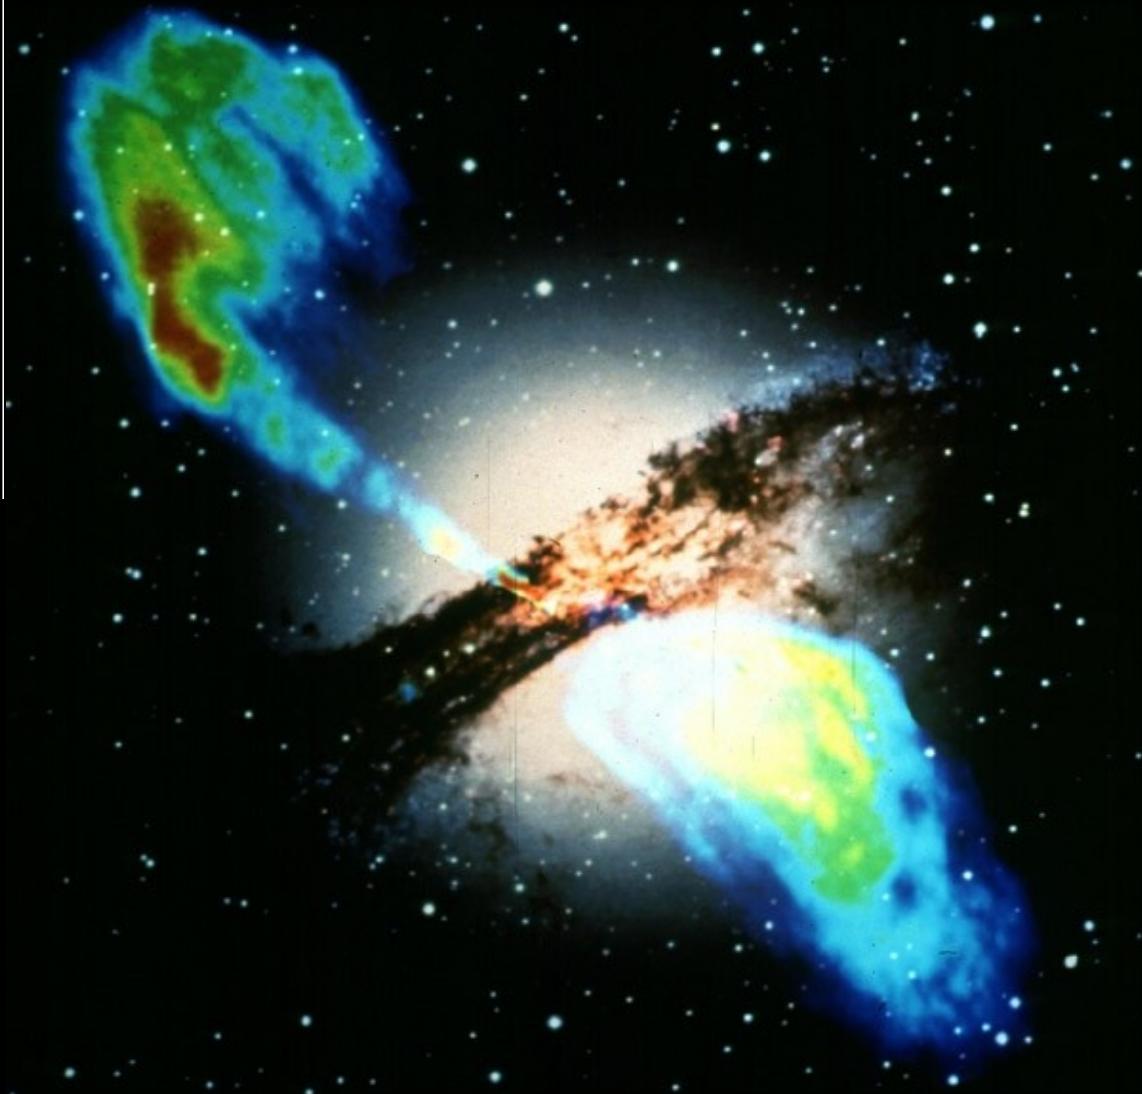

Radio lobe size ~ 200 kpc!

The radio lobes are fed by relativistic jets; we see only one sided jet due to relativistic beaming.

Cen A

(distance ~ 2.5 Mpc)

HST & 6 cm VLA

Crab nebula (Plerion)

Blue: x-ray

Red: optical

Green:radio

**Luminosity $\sim 10^{38}$ erg/s
(mostly x-ray & gamma)**

Synchrotron radiation:

(linear polarization of 9%
averaged over nebula).

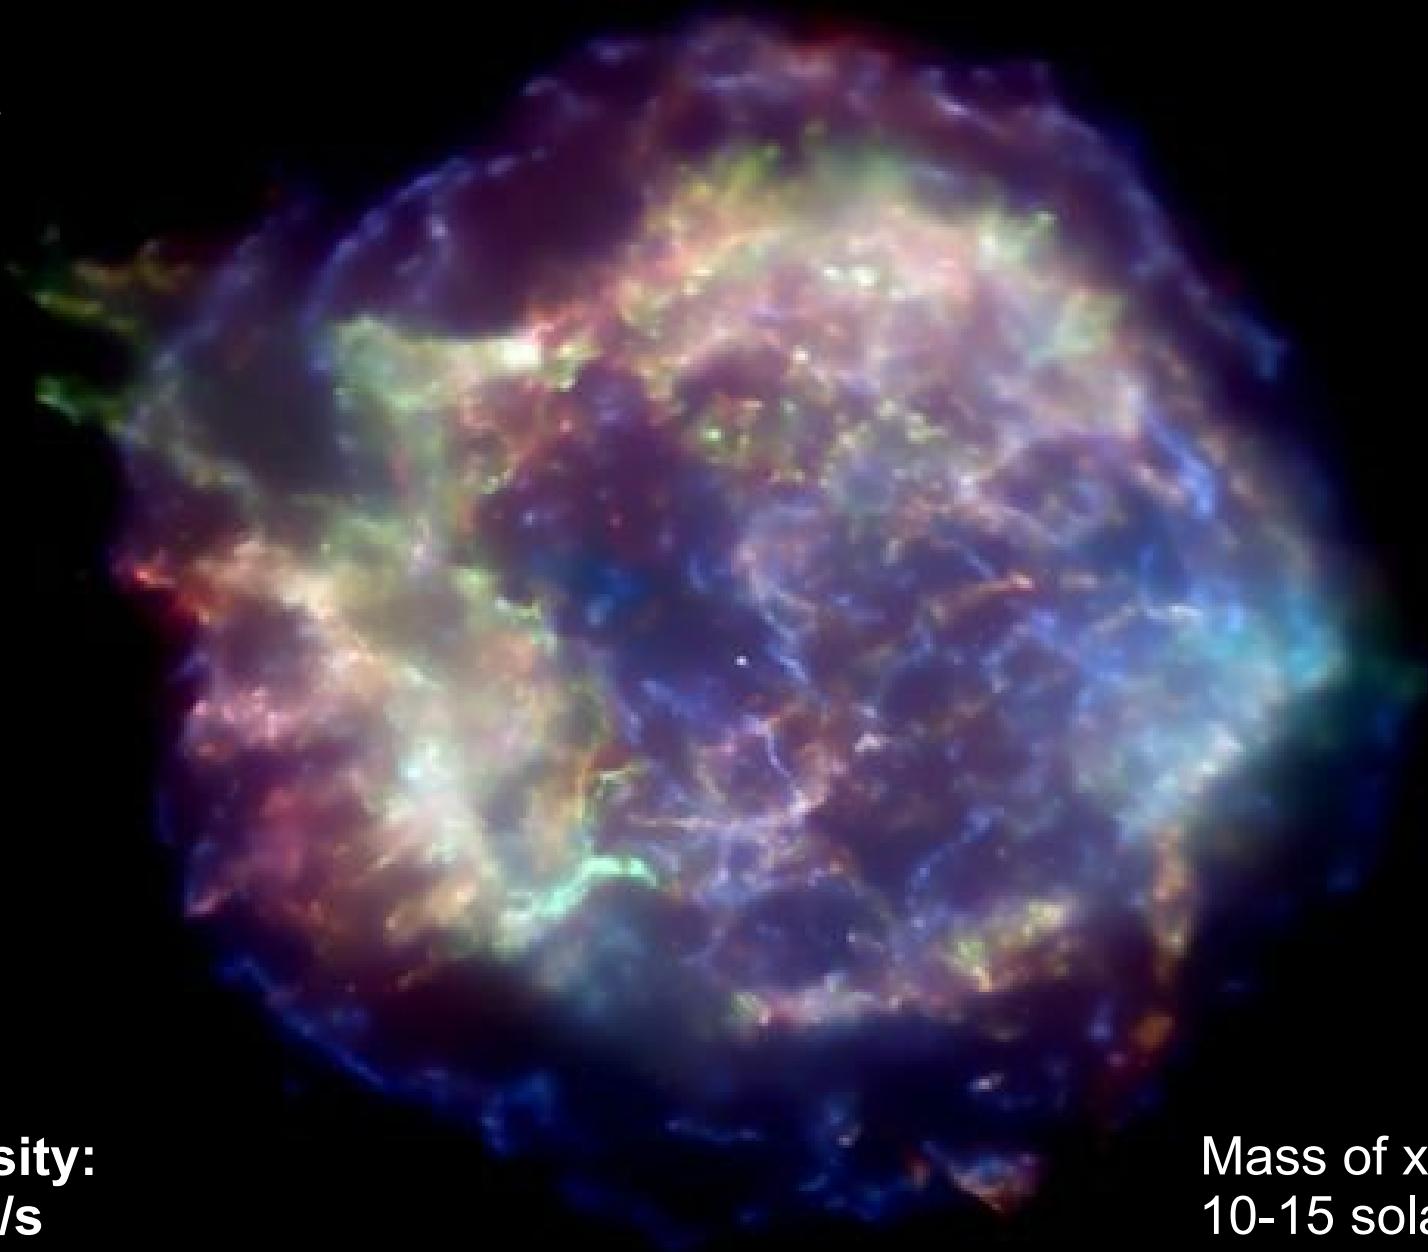

Electrons with energy $> 10^{14}$ ev
are needed for emission at 10 kev;
lifetime for these e's < 1 year.
So electrons must be injected
continuously & not come from SNe.

SN remnant: Cas A (3-70 kev; Chandra) (Plerion)

SNe II remnant

Age 300 yr
(1670 AD)

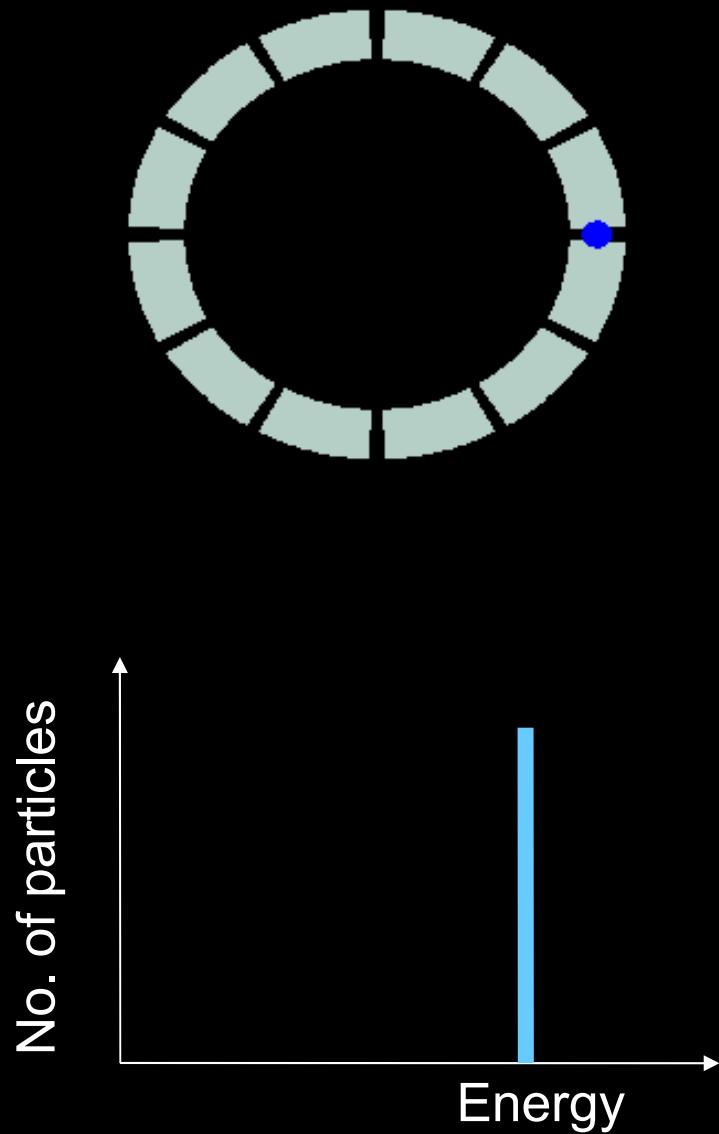

X-ray luminosity:
 3.8×10^{36} erg/s

Mass of x-ray gas
10-15 solar mass.

The early days

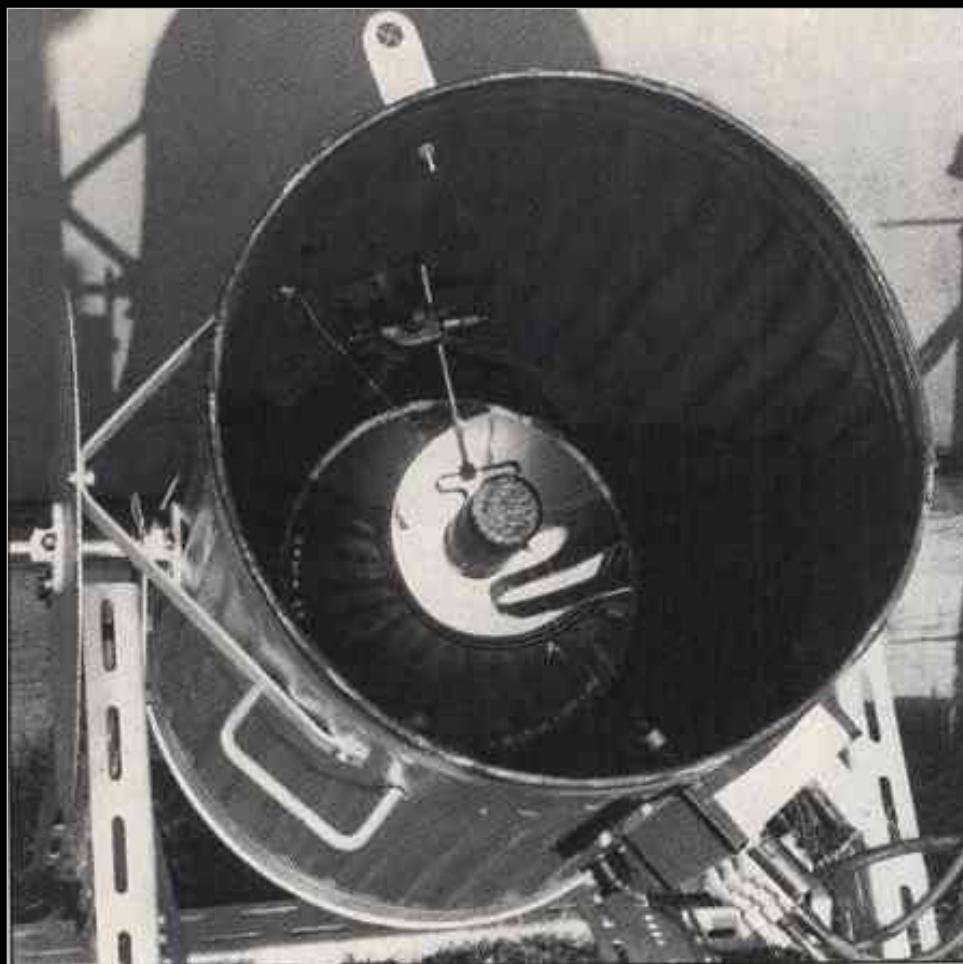

February 21, 1953 NATURE

Light Pulses from the Night Sky associated with Cosmic Rays

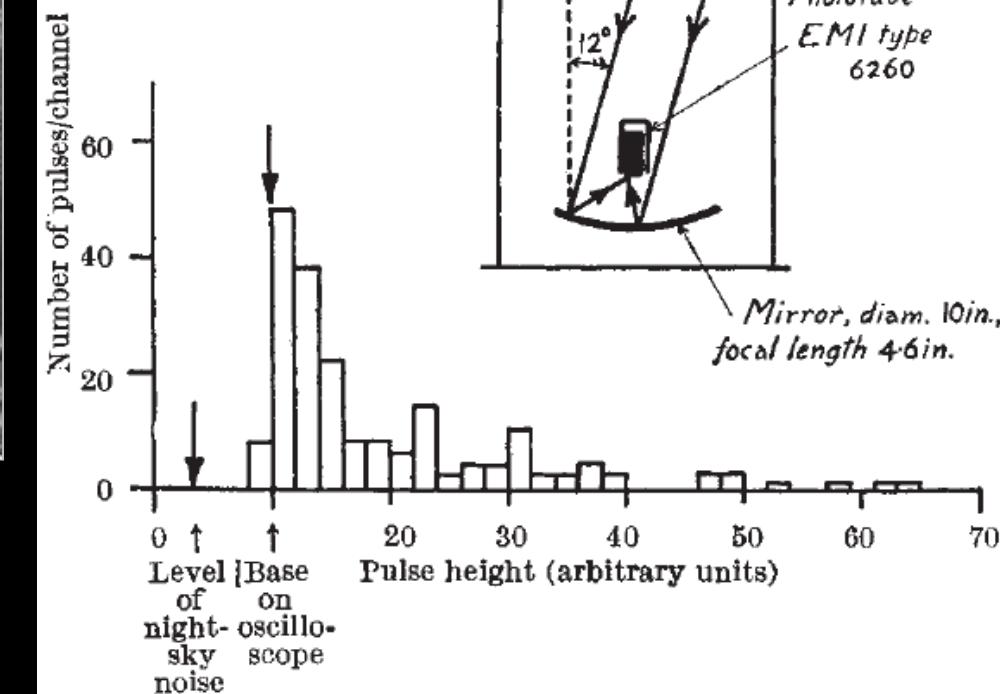

IN 1948, Blackett¹ suggested that a contribution approximately 10^{-4} of the mean light of the night-sky might be expected from Čerenkov radiation² produced in the atmosphere by the cosmic radiation. The purpose of this communication is to report the results of some preliminary experiments we have made using a photomultiplier, which revealed the

thank Mr. W. J. Whitehouse and Dr. E. Bretscher for their encouragement, and Dr. T. E. Cranshaw for the use of the extensive shower array.

Background modeling techniques

Prior:

Key point: Whatever the power of a given analysis technique

There is an irreducible Background due to CR's

as opposed to e.g. Space-based g-ray astronomy

Only a statistical determination of a signal $N_{\text{exc}} = N_{\text{On}} - \alpha * N_{\text{Off}}$

The sensitivity of a Cherenkov telescope system depends on our ability to:

A- reject the background: typically shape-cuts yield $\sim 10^2$ rejection

B- understand and minimize the systematics

Some historical “background”

Single telescopes such as Whipple or CAT:

- had a small field of view ($\sim 2.5^\circ$ - 3°)
- were sensitive only to point-like sources : Crab, Mkn421, Mkn 50, ...

The Background determination was originally made in the so-called On/Off mode:

- On : source centred in the field of view (fov)
- Off: data taken on an “empty” field observed typically with $\text{RA}_{\text{Off}} = \text{RA}_{\text{On}} \pm 30'$

Motivations:

- The threshold of a Cherenkov telescope is a function of zenith angle
the altitude of the shower maximum rises as a f (zenith)
- The atmosphere is part of the detection instrument, the calorimeter
variations of the atmospheric conditions (transparency, haze, pressure, ...) imply variations of the “detector” characteristics:
threshold, effective area, rejection factor, ...

Drawback:

- One loses half of the dark period time to do Off observations

The ping-pong/tracking or wobble mode or how to save time

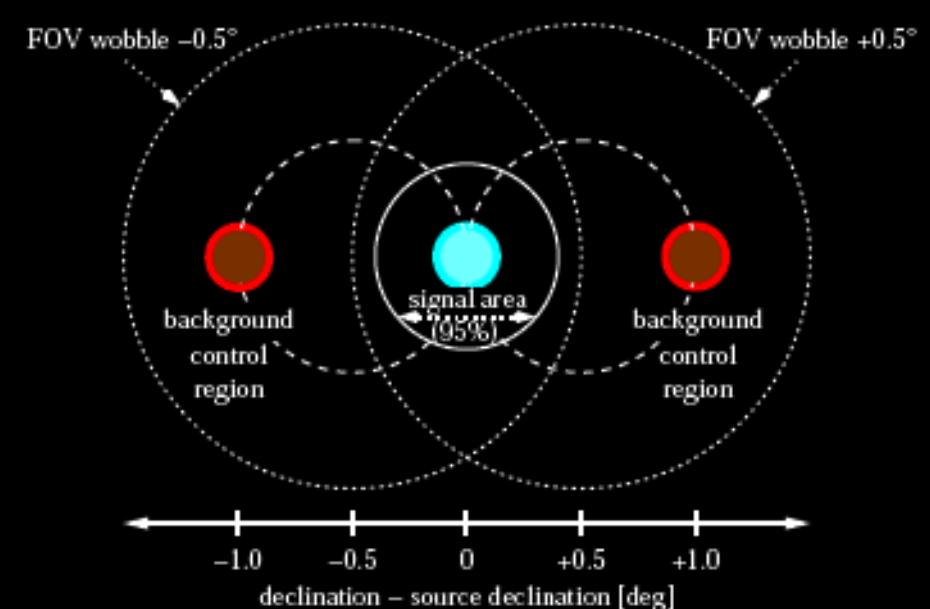

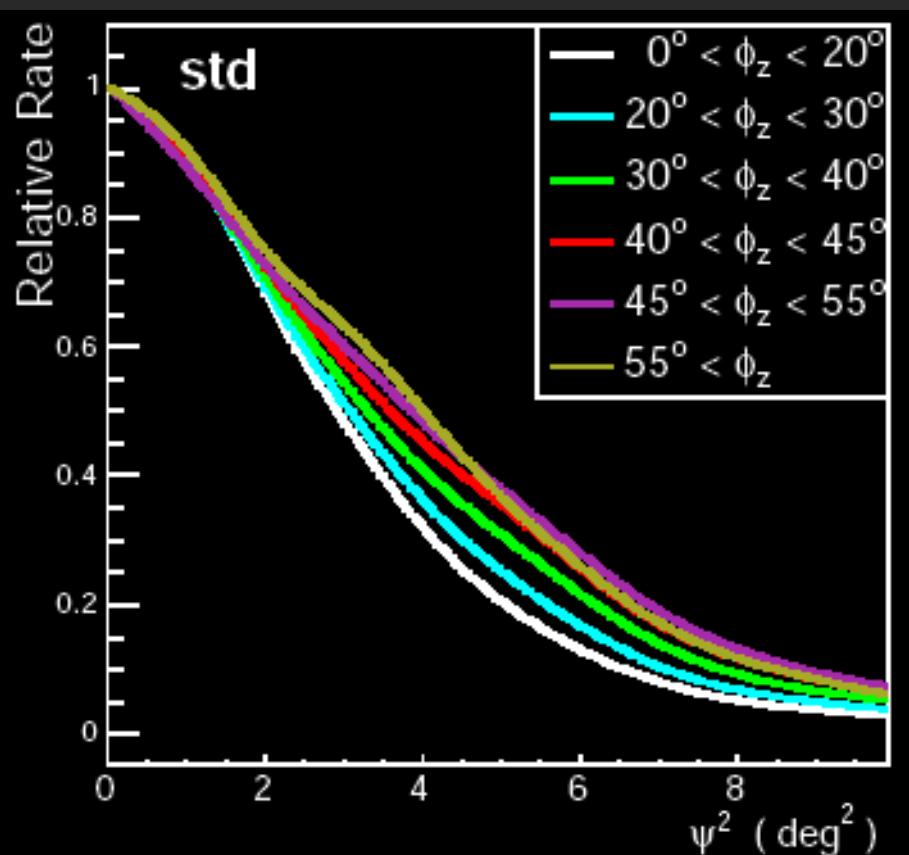

Pioneered by the Whipple collaboration (tracking) and subsequently developed by HEGRA

- Offset the source in the fov by $\pm 0.5^\circ$
alternatively

- Estimate the background from the opposite side of the fov: Mirrored Bg, Ref ected

Why the opposite side/ fov ?

The acceptance (detection efficiency) is not uniform but is radially decreasing :

The position and extension of the candidate source should be known

Assumes : azimuthal symmetry

The Reflected/multiple background model

Can be extended to get higher statistics on Off:

Average over the fov at same radial distance

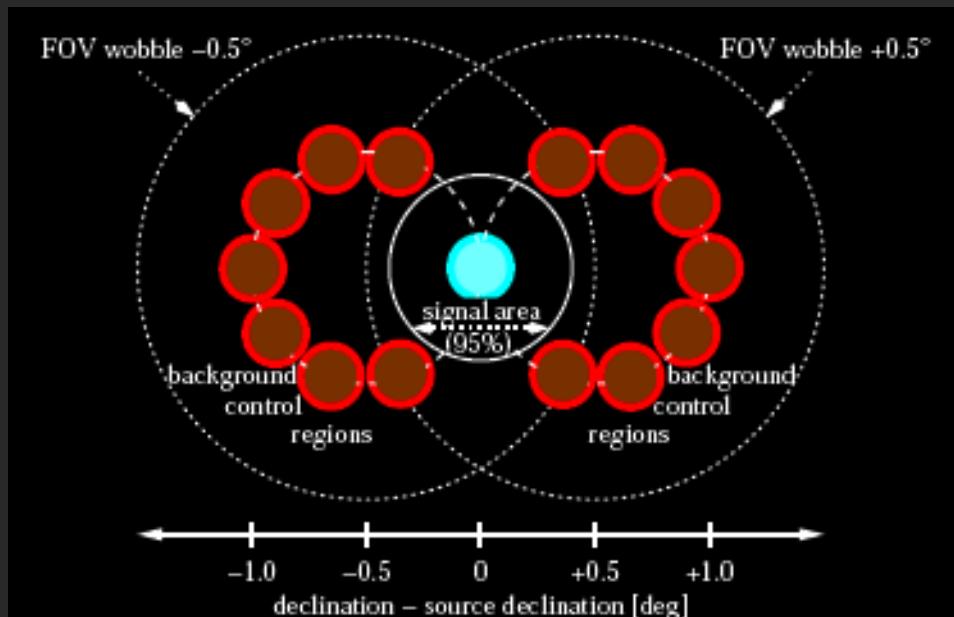

Typically the source is offset by 0.5° to 0.7°
(point-like sources)

⇒ a factor 7 to 10 more Off statistics

For an extended source offset is increased
But for very large sources On/Off method
becomes mandatory

**Again ssumes : azimuthal symmetry but less
subject to systematics due to averaging**

**One should avoid contamination of the background estimate by
 γ -rays from a neighbouring source ⇒ forbid known sources' positions
for being used as background**

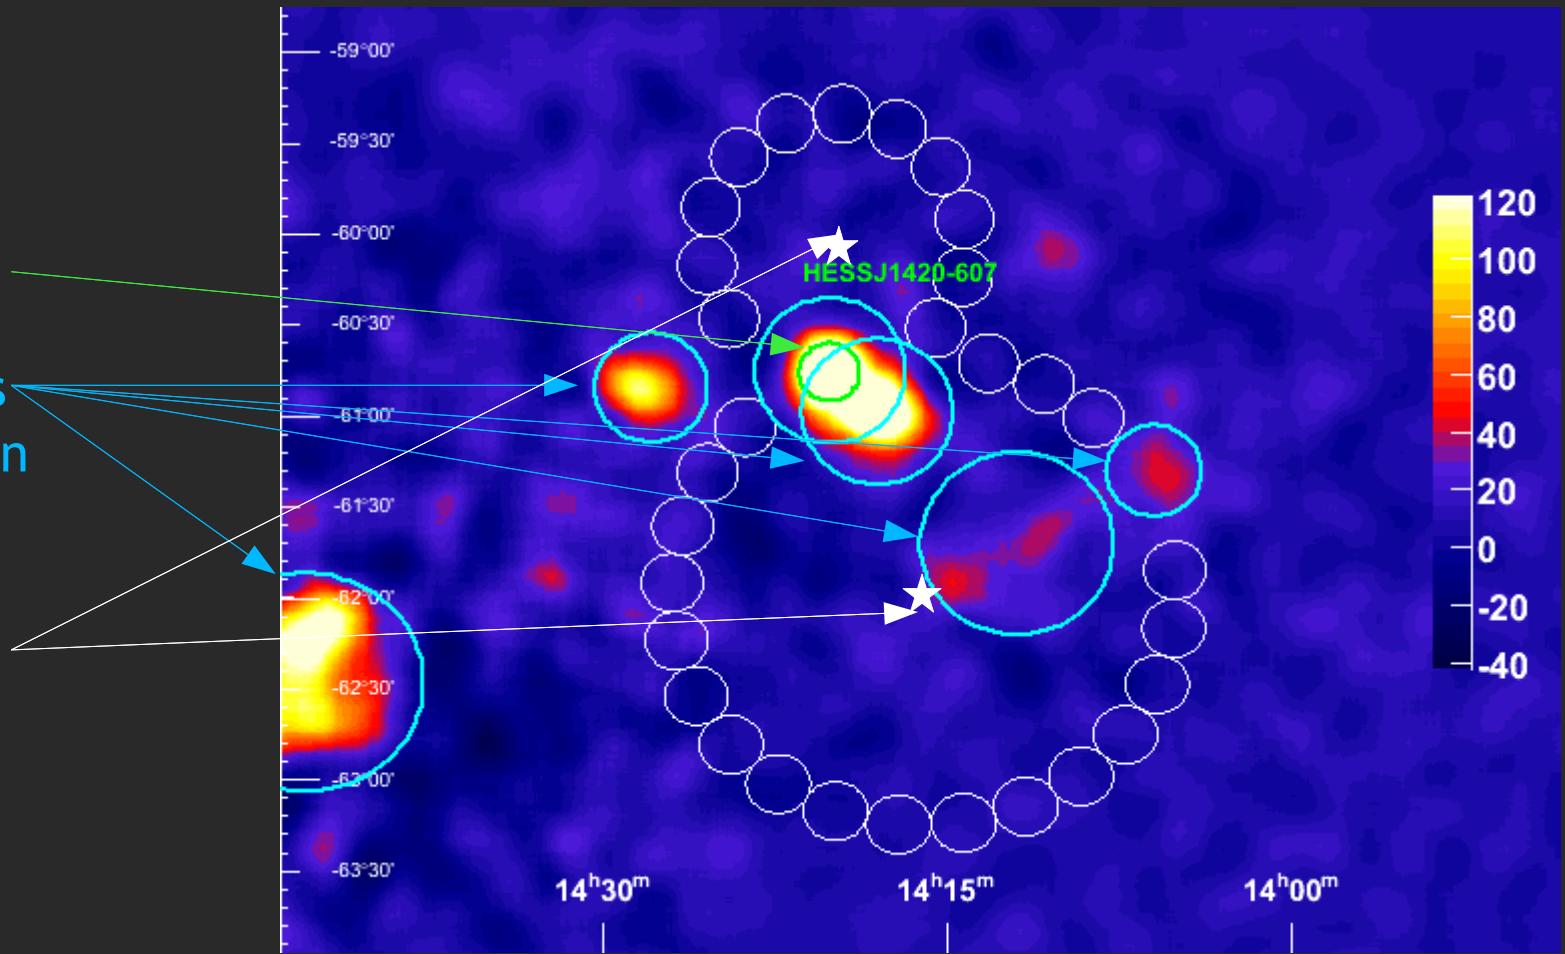

**The position and extension of the candidate source should be known:
AGN's : point-like, known
Galactic sources: need to measure those properties before...**

A concrete example: the Kookaburra ($\mathrm{l} \sim 313.4^\circ$)

The region of interest:
HESS J1420-607
Exclusion regions
For Bg estimation

Center of fov
for
2 runs

For large data-sets, various offsets \Rightarrow Different α :need for a proper averaging procedure to weight runs: use radial acceptance

To avoid contamination by γ -rays from a neighbouring source one needs to know their positions and extensions : need for 2D maps of Bg

Background models : some general points

$$N_{\text{exc}} = N_{\text{On}} - \alpha * N_{\text{off}}$$

A Background model has to provide N_{off} and α

The significance is larger for smaller α

But the systematics may be larger for $\alpha \ll 1$

Different goals \Rightarrow different methods

Detection of a source: N_{off}, α global

Spectrum : $N_{\text{off}}(E), \alpha(E)$

Morphology, Sky maps : $N_{\text{off}}(x,y), \alpha(x,y)$

Morphology, Sky maps=f(E) : $N_{\text{off}}(x,y,E), \alpha(x,y,E)$

Note : in general α should not depend on E to minimize systematics

The Ring background model : 2D maps

A ring can be defined around each trial position in the fov (celestial coordinates)

α is the ratio of the ring solid angle (radius 0.5° - 0.8° typically)
to the trial source region

α is typically $\sim 1/7$.

But a given ring covers areas with different offsets wrt the fov centre

\Rightarrow need for an acceptance correction function

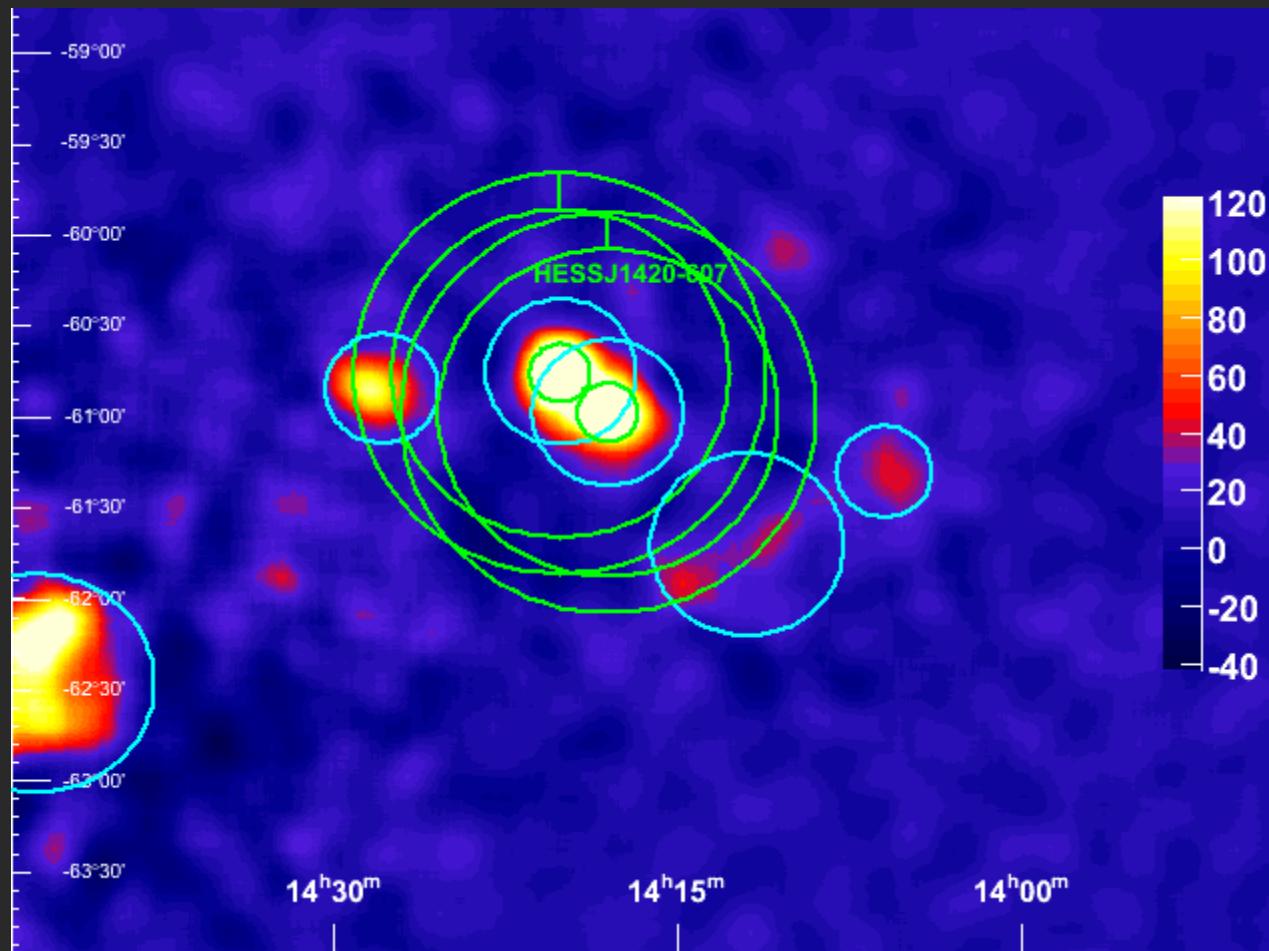

Also avoid the known sources
to prevent **γ -ray** contamination

\Rightarrow further correction of α

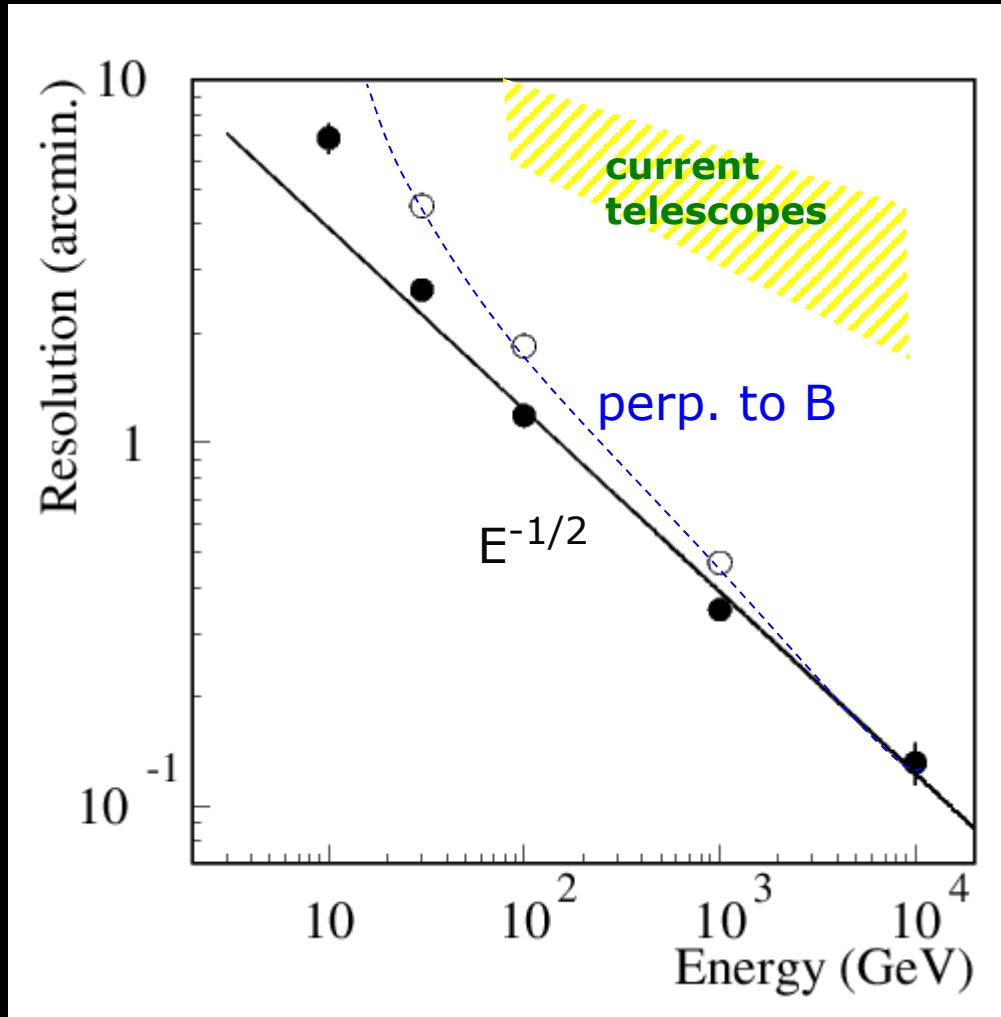

Due to overlap of rings
neighbouring pixels are
correlated

NOT suitable for crowded fov

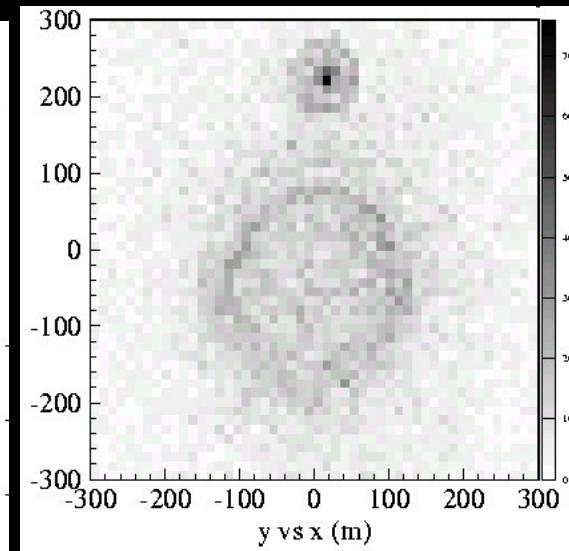

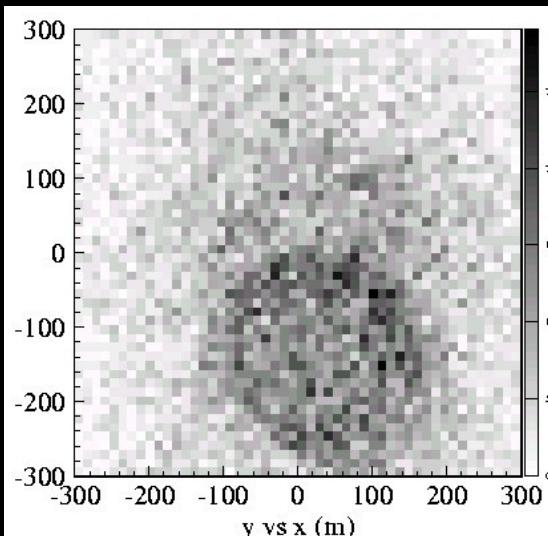

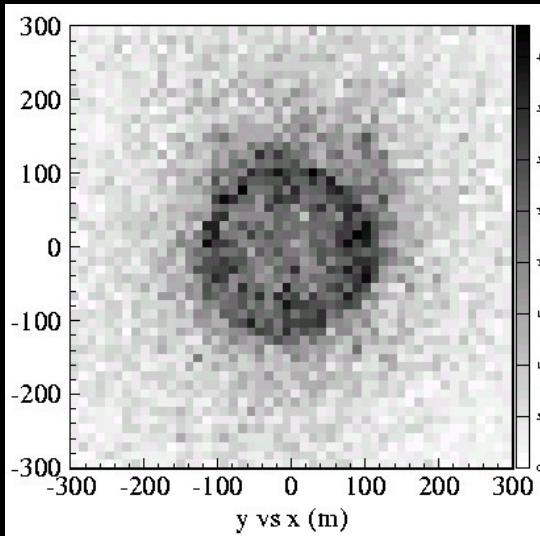

NOT suitable for Spectra :
Radial acceptance= $f(E)$ strongly

Angular resolution limit

.... assuming that
impact point and
direction of ALL
Cherenkov photons are
measured perfectly

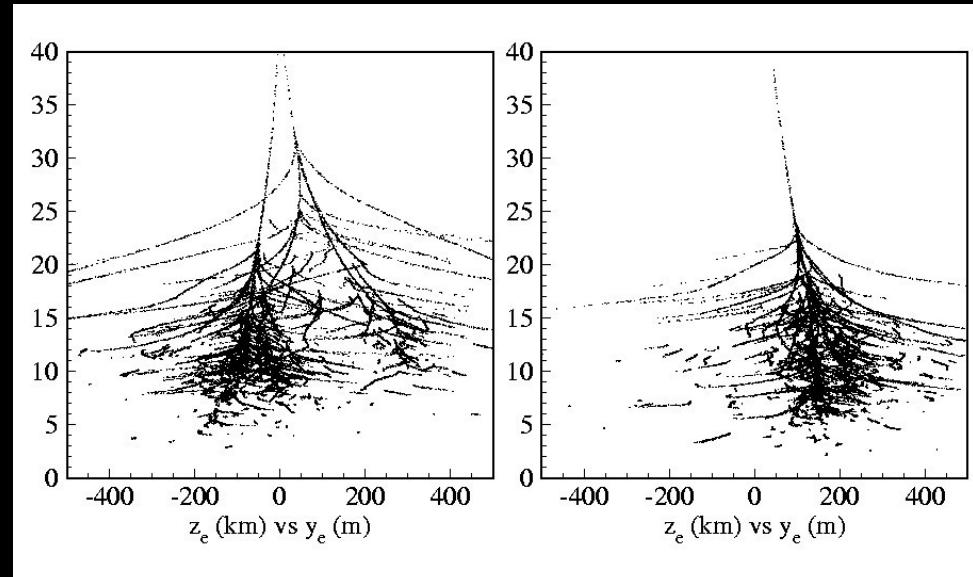

Geomagnetic deflection of primary pair limits angular resolution at low energies
(starts to become relevant at a few 100 GeV)

Effect:

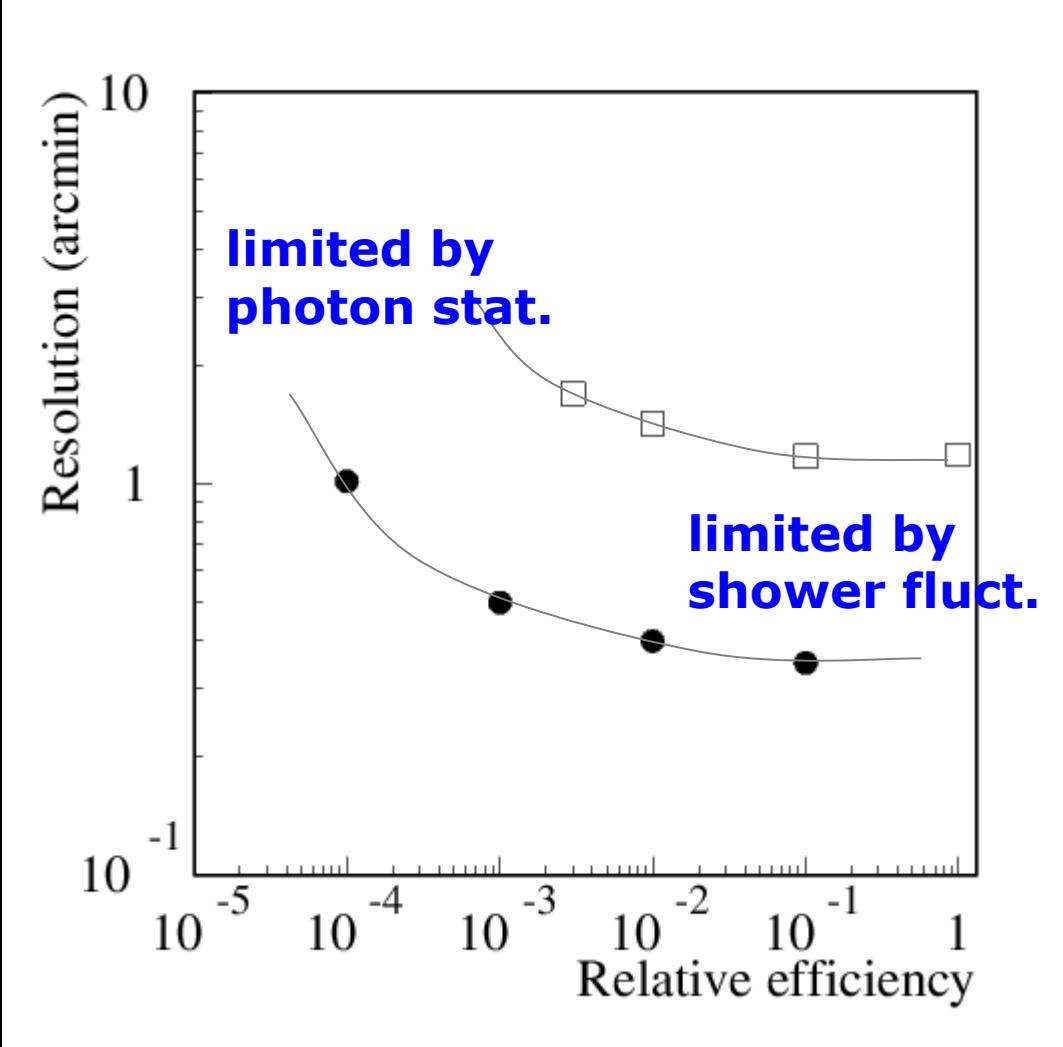

Change of effective shower direction

Depends on energy splitting in primary conversion

Cannot be corrected

Angular resolution limit

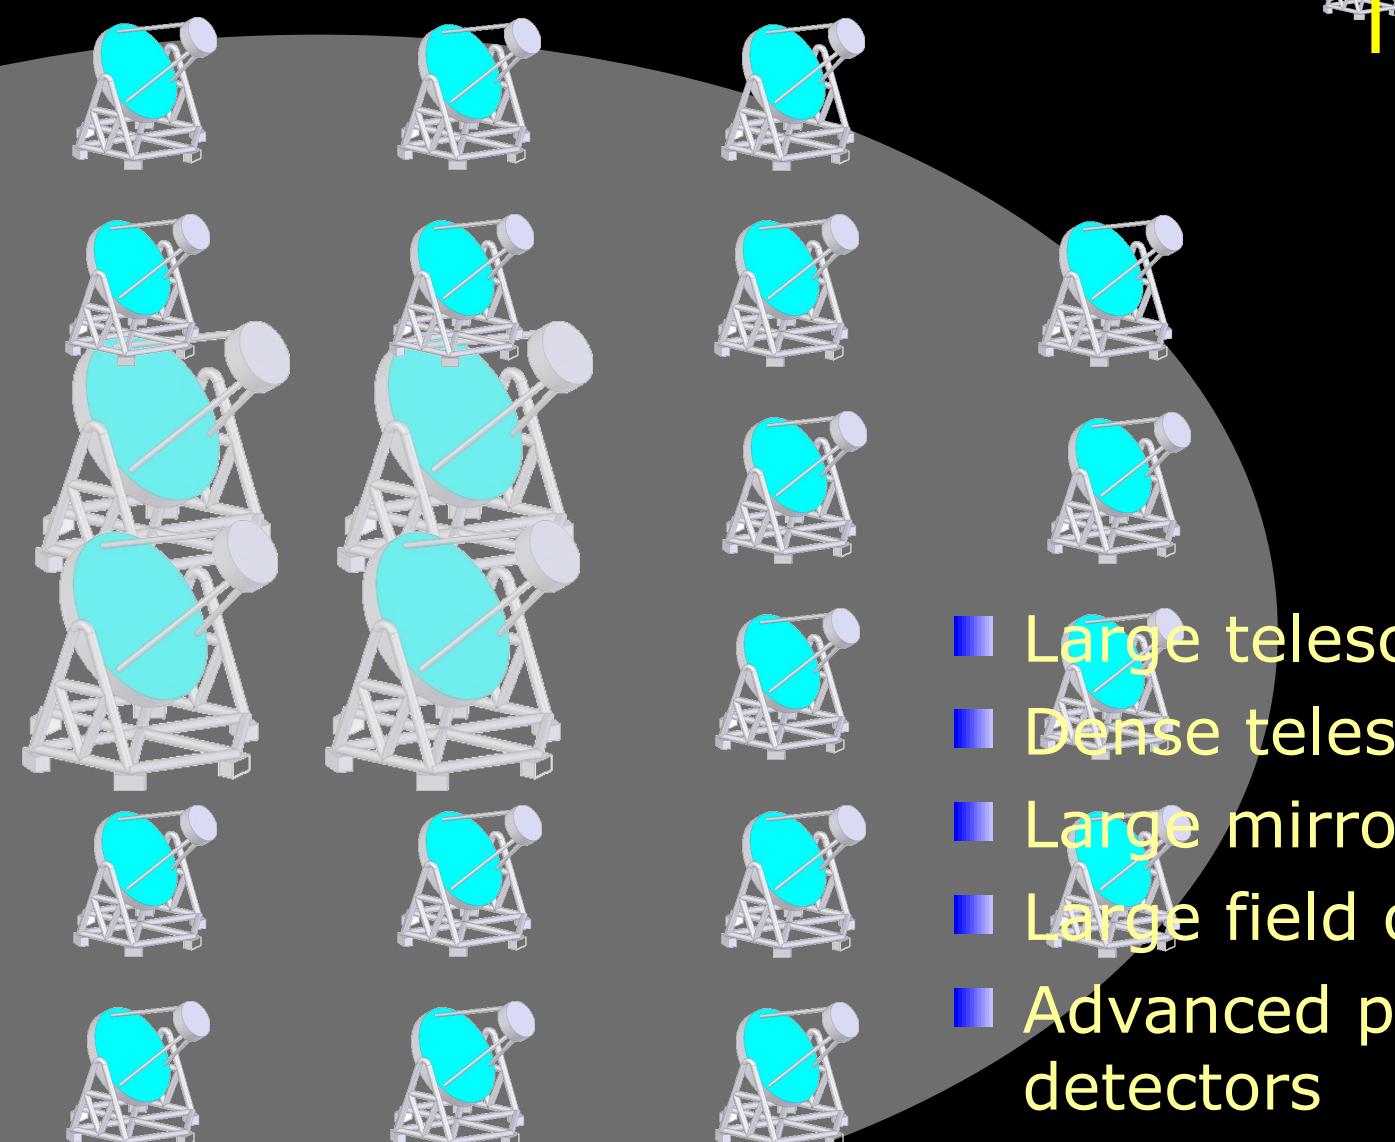

► Need to cover 0.1% or better 1% of area (assuming PMTs as detectors)

H.E.S.S.: 0.7%
but only over 240 m x 240 m

Relative to
PMT efficiency

The future

Not to scale !

- Large telescope arrays
- Dense telescope arrays
- Large mirror area
- Large field of view
- Advanced photon detectors
- Advance signal & trigger processing
