WHERE WE LOOK

HOW WE LOOK

Dark Matter in Galaxies

Die Rotverschiebung von extragalaktischen Nebeln

von F. Zwicky.

(16. II. 33.)

Inhaltsangabe. Diese Arbeit gibt eine Darstellung der wesentlichsten Merkmale extragalaktischer Nebel, sowie der Methoden, welche zur Erforschung derselben gedient haben. Insbesondere wird die sog. Rotverschiebung extragalaktischer Nebel eingehend diskutiert. Verschiedene Theorien, welche zur Erklärung dieses wichtigen Phänomens aufgestellt worden sind, werden kurz besprochen. Schliesslich wird angedeutet, inwiefern die Rotverschiebung für das Studium der durchdringenden Strahlung von Wichtigkeit zu werden verspricht.

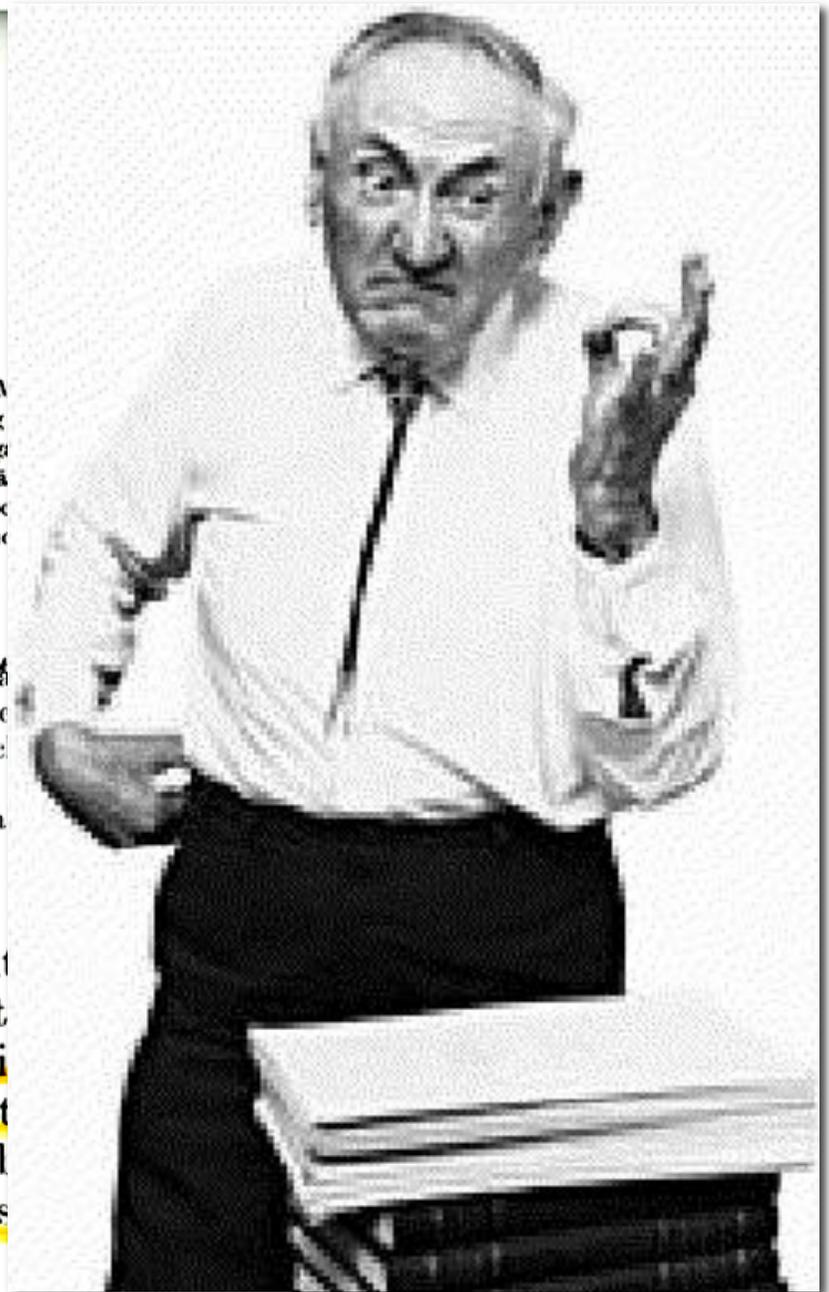

§ 1. Einleitung.

Es ist schon seit langer Zeit bekannt, dass es im Weltall gewisse Objekte gibt, welche, wenn mit kleinen Teleskopen beobachtet, als stark verschwommene, selbstleuchtende Flecke erscheinen. Diese Objekte besitzen verschiedenartige Strukturen. Manche sind kugelförmig, oft elliptisch, und viele unter ihnen ha-

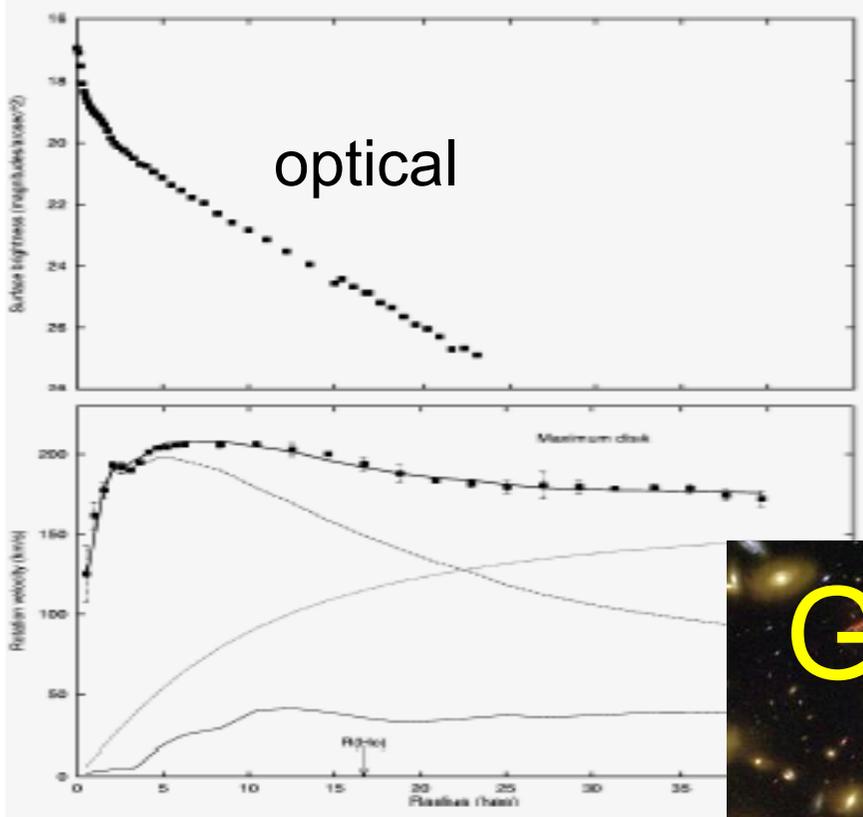

Rotverschiebung extragalaktischer Nebel.

Um, wie beobachtet, einen mittleren Dopplereffekt von 1000 km/sek oder mehr zu erhalten, müsste also die mit der Materie im Comasystem mindestens 400 mal grösser sein als die von Beobachtungen an leuchtender Materie abgeleitet. Nach dies bewahrheiten sollte, würde sich also das übliche Resultat ergeben, dass dunkle Materie in sehr viel grösserer Menge vorhanden ist als leuchtende Materie.

2. Man kann auch annehmen, dass das Comasystem sich nicht im stationären Gleichgewicht befindet, sondern dass die ganze verfügbare potentielle Energie als kinetische Energie er-

only upper limits....**

FERMI/HESS prediction: final state gamma rays

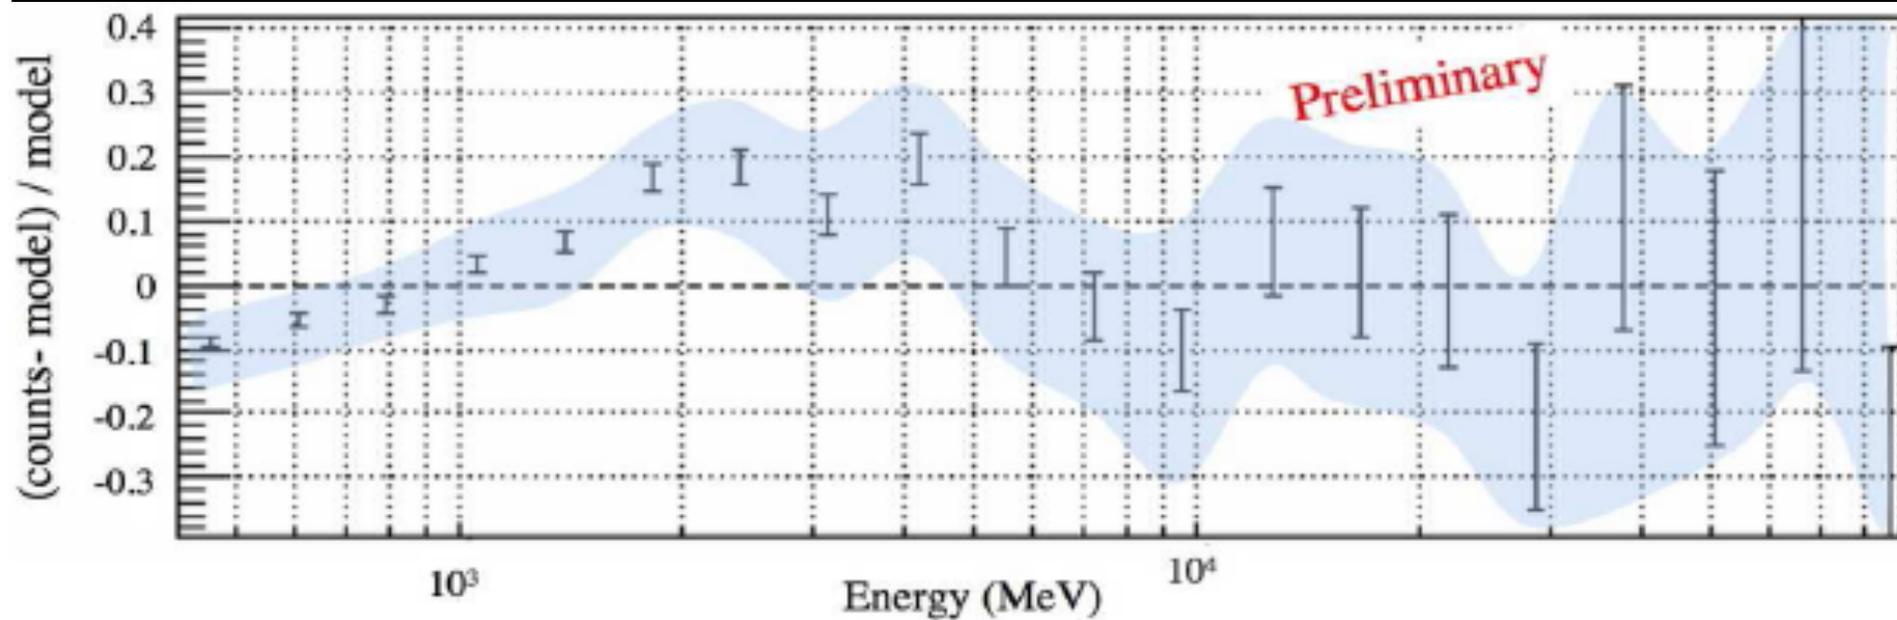

$$\text{DM DM} \rightarrow \mu^+ \mu^-, M = 1.3 \text{ TeV}, \sigma v = 2.8 \times 10^{-23} \text{ cm}^3/\text{s}$$

FERMI galactic centre residuals

Did we prematurely abandon a dark matter contribution in the Galactic Centre?

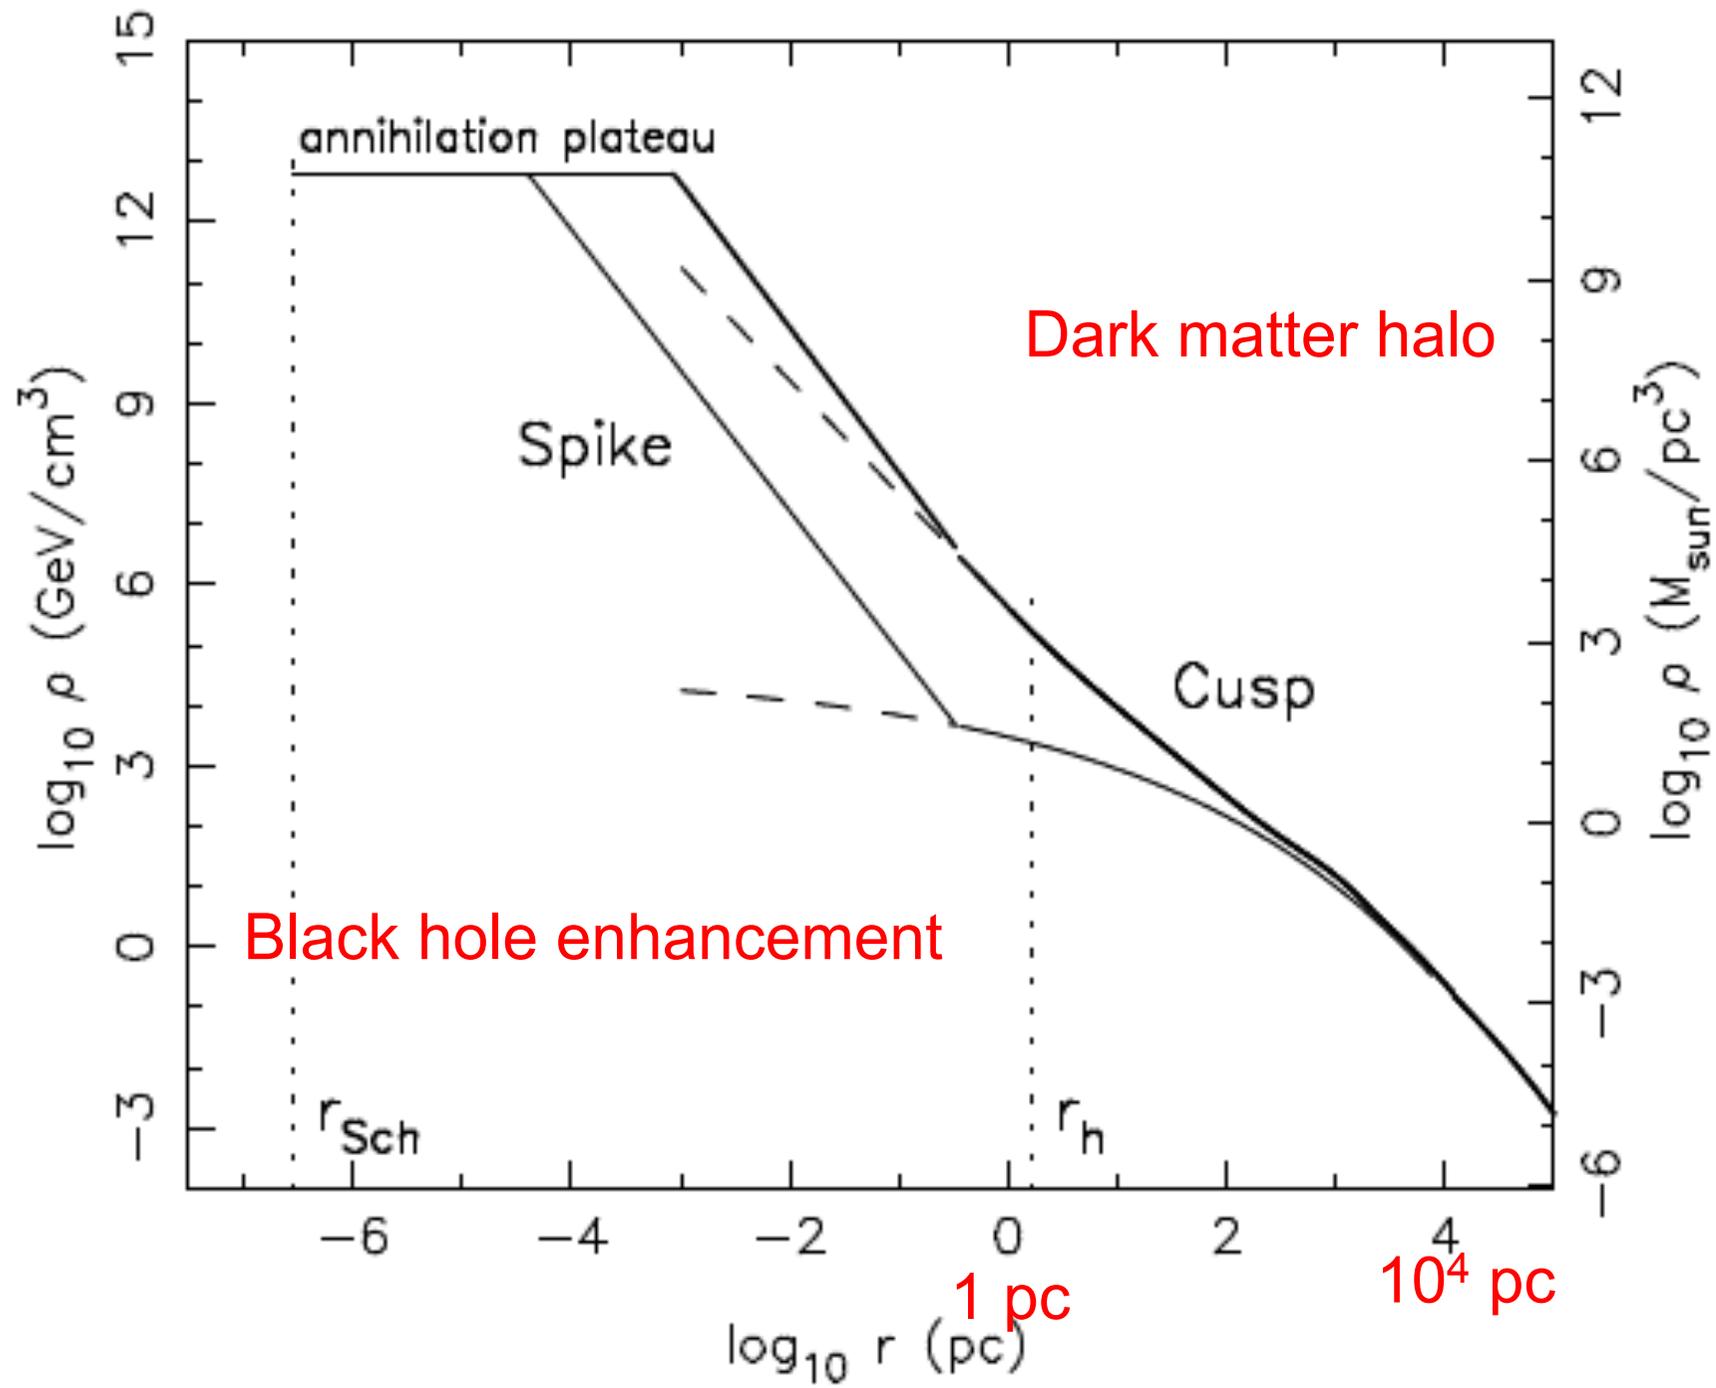

CDM cusp steepens by adiabatic growth
of IMBH: $\rho \propto r^{-\gamma} \Rightarrow \rho \propto r^{-\gamma'}$, with $\gamma' = \frac{9-2\gamma}{4-\gamma}$

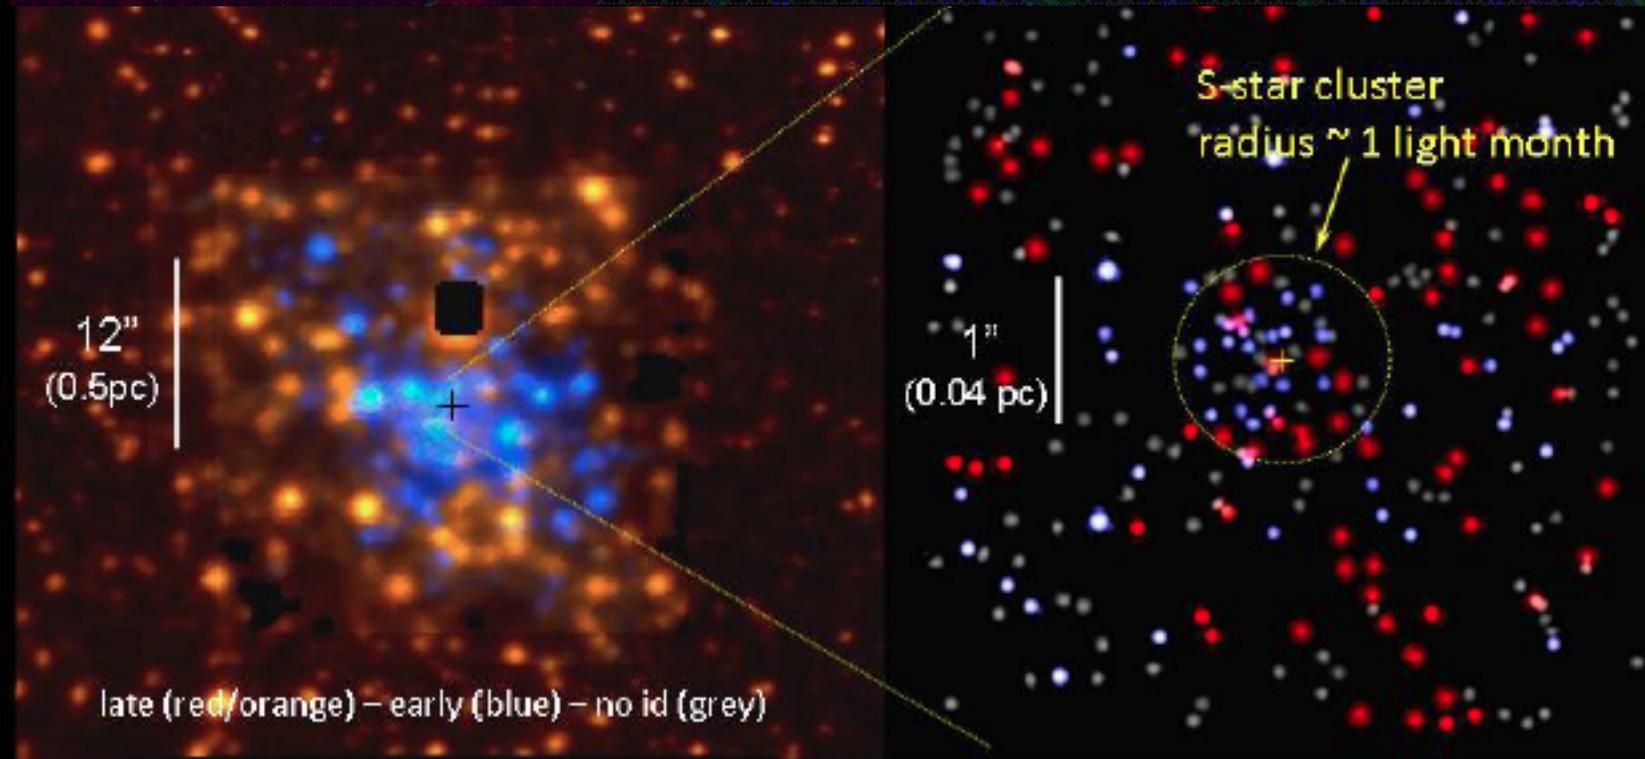

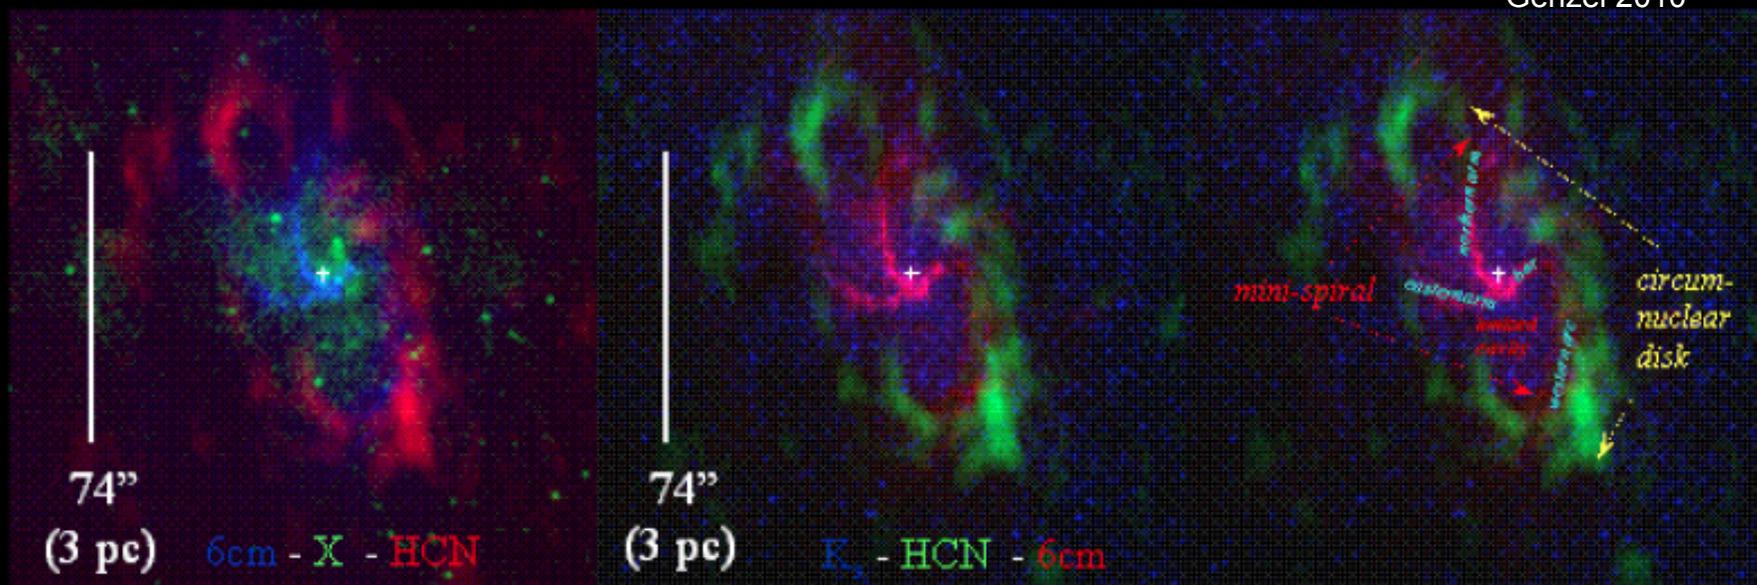

Annihilation rate is amplified within a
radius $GM_{bh}/\sigma^2 \sim 0.003(M_{BH}/10^5 M_{\odot})\text{pc}$

a local boost is natural in gravitationally bound
spike around Sag A* black hole $4 \times 10^6 M_{\text{sun}}$

Dynamical heating reduces peak density

DM predicts exponential cut-off + no variability

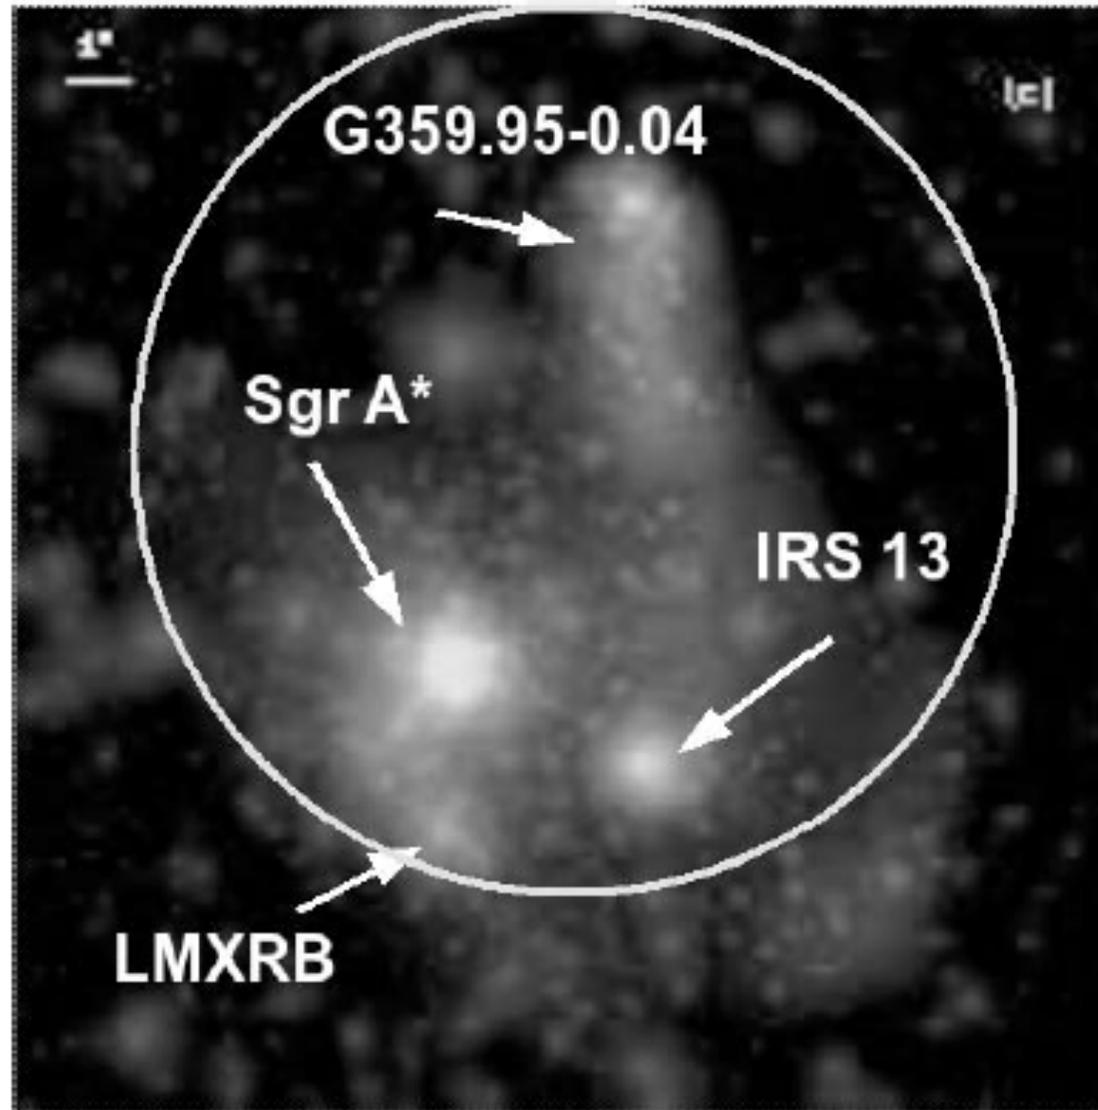

FIGURE 1. Chandra X-ray and NACO Near-infrared Composite of the Galactic center region [4]. The circle marks the systematic (and therefore irreducible) H.E.S.S. uncertainty region of 6".

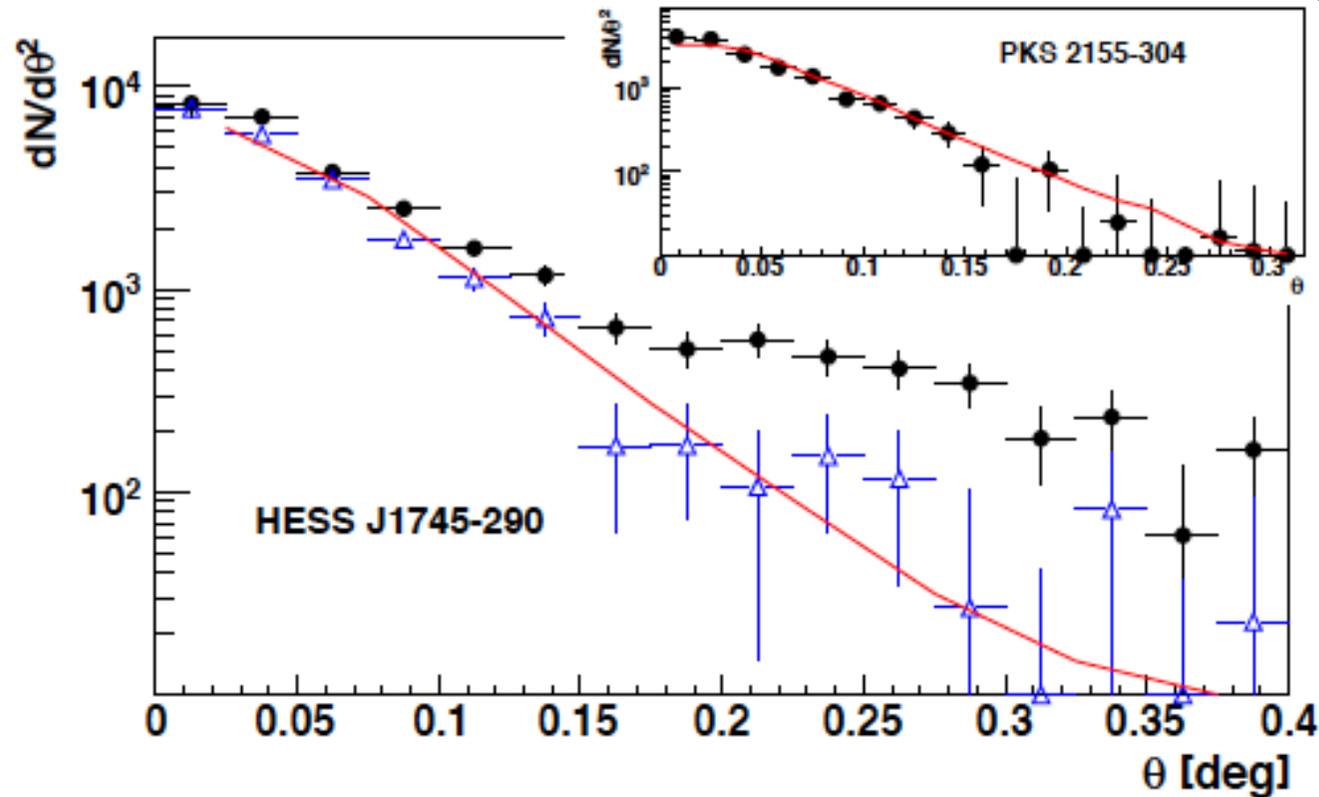

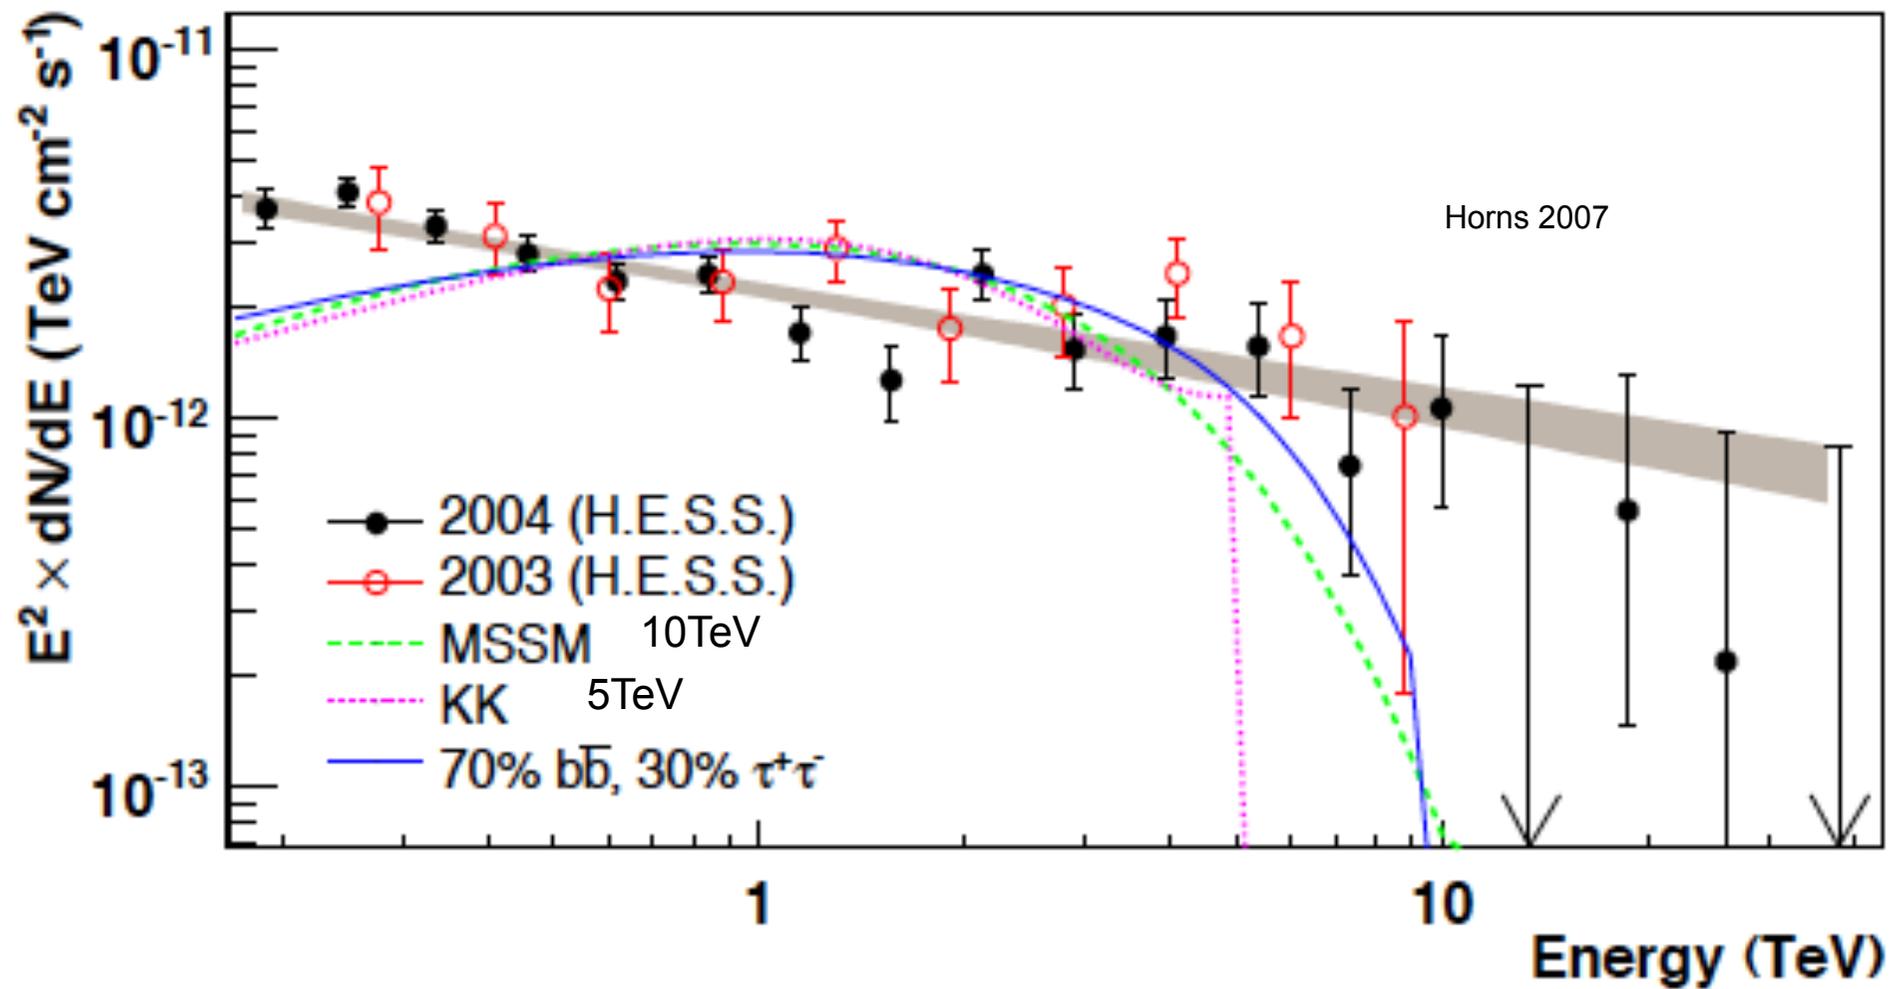

Fig. 2. Radial surface brightness profile of the gamma-ray emission (number of gamma-ray events per solid angle) from the Galactic center: The solid points indicate the number of gamma-ray events detected from the Galactic center and the environment up to an angular separation of $\theta = 0.4^\circ$ while the open points show the surface brightness after subtracting off the diffuse emission from the Galactic ridge. The solid line represents the expected distribution of gamma-rays for a point-like source taking into account varying zenith angles of the observation. As an example for an observation of a point-like source, the signal obtained from the Active Galactic Nucleus PKS 2155-304 is shown in the inlaid figure.

The Galactic Centre black hole:

exponential spectrum preferred?

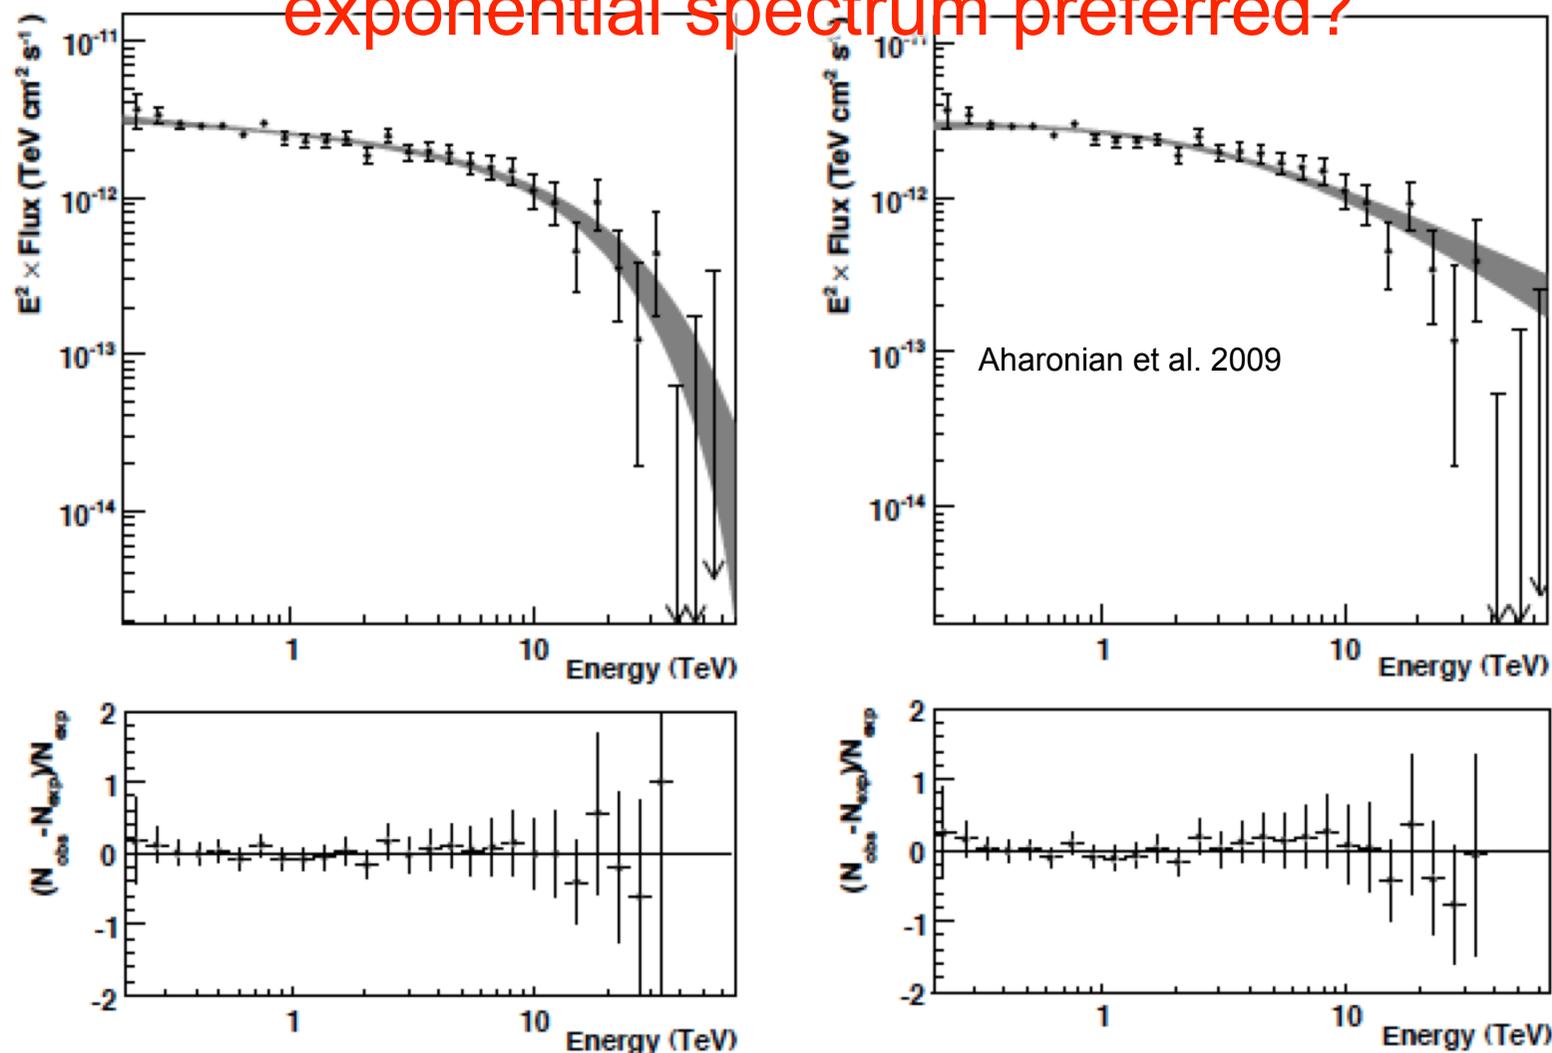

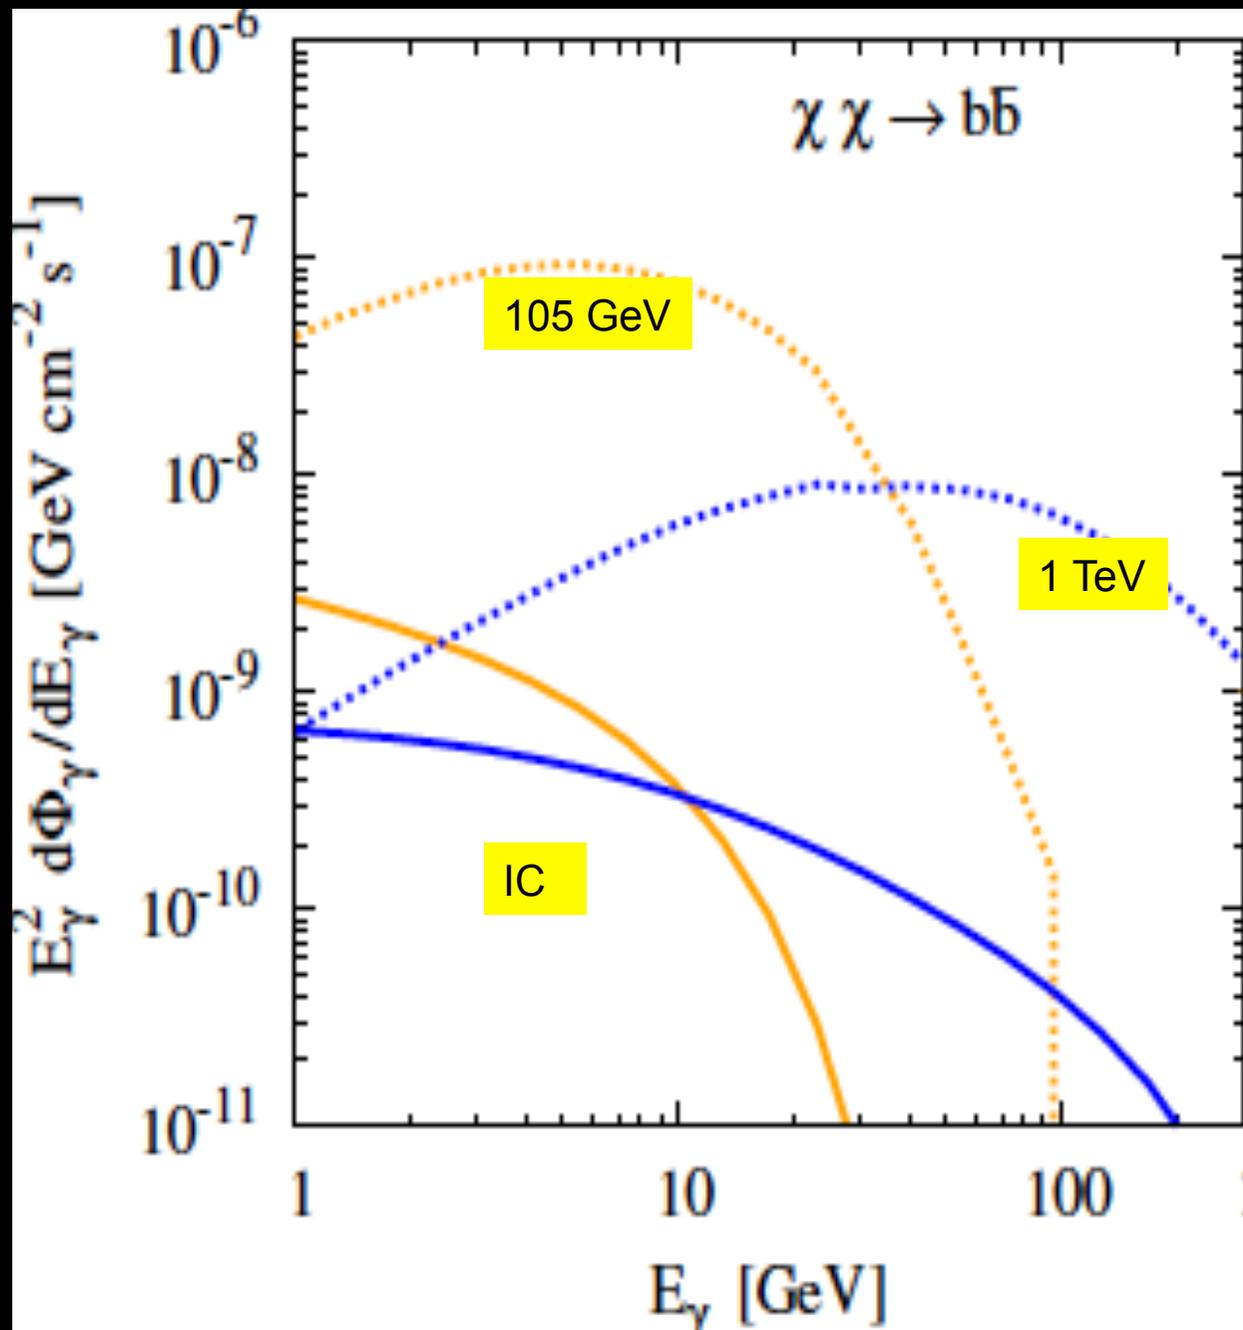

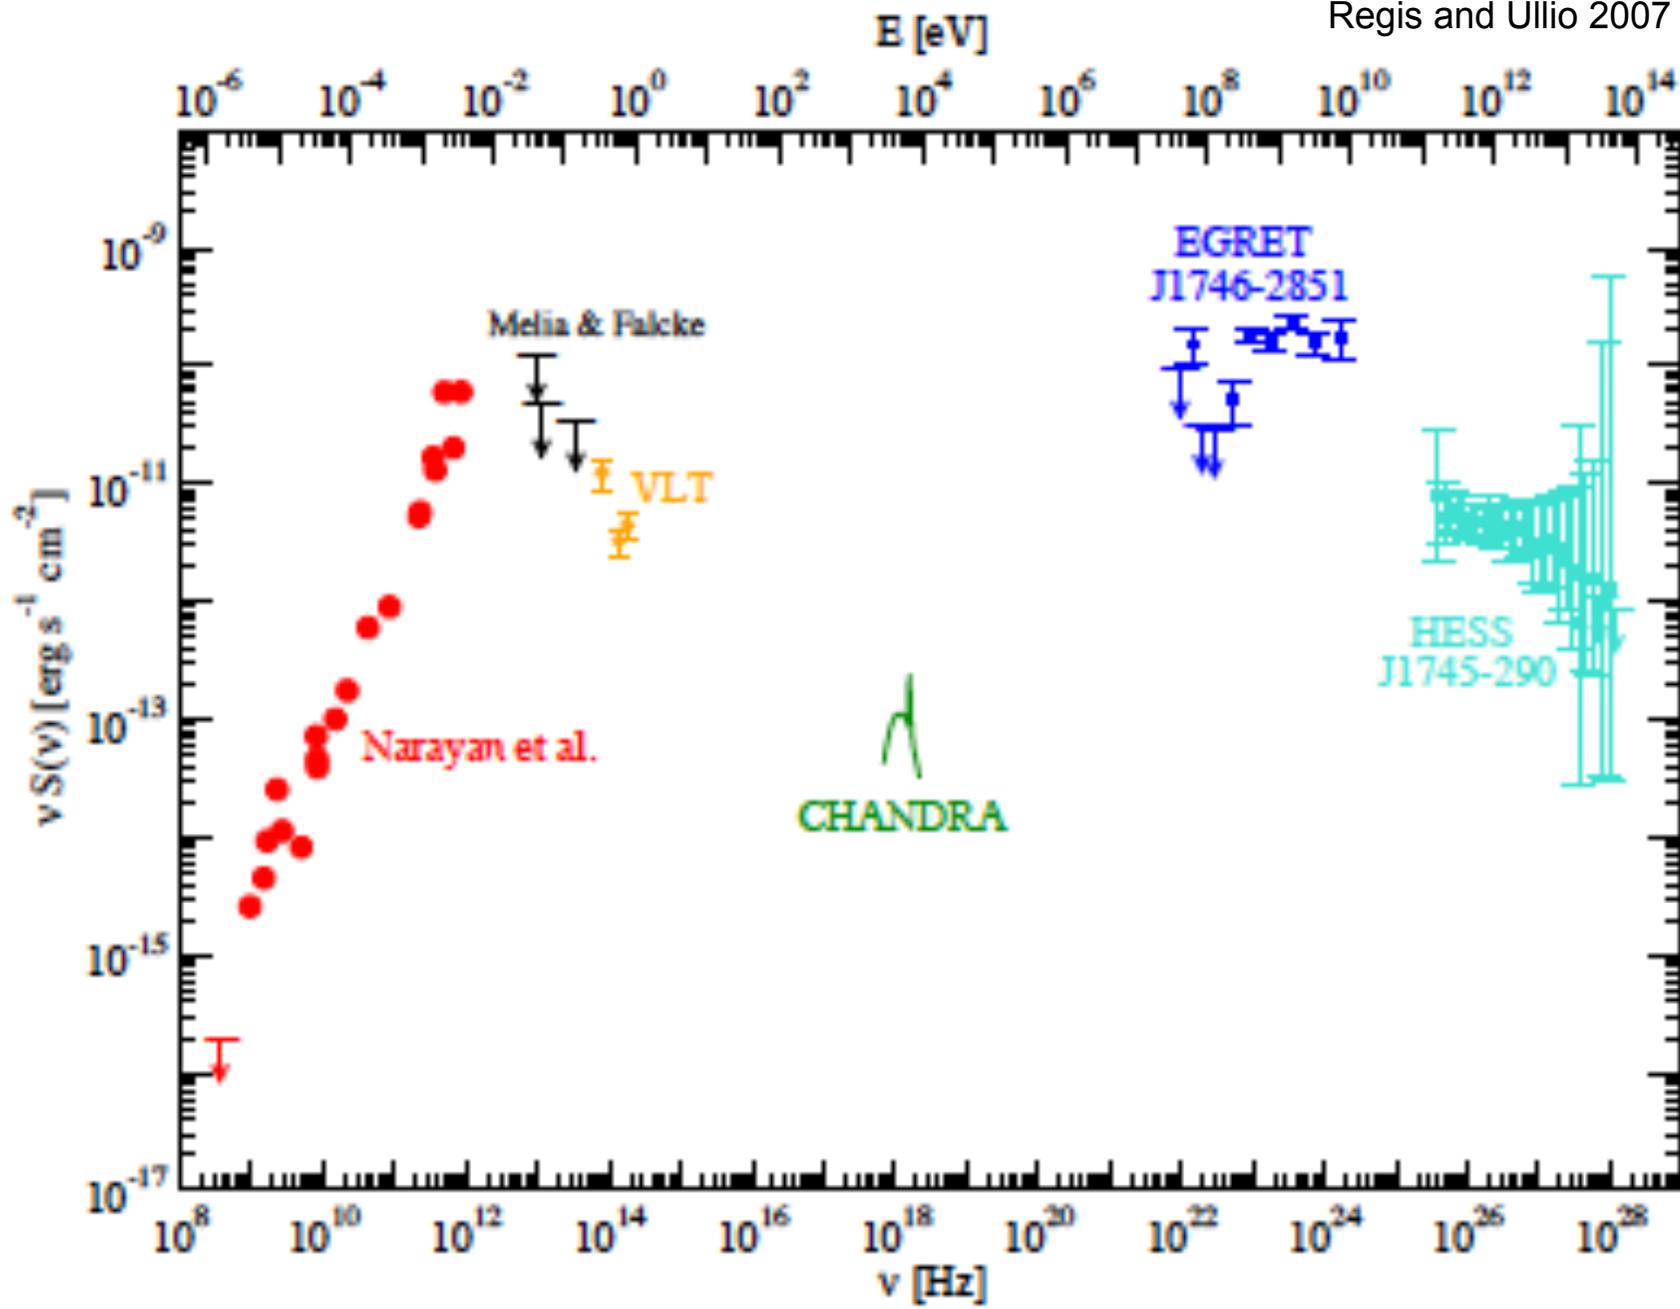

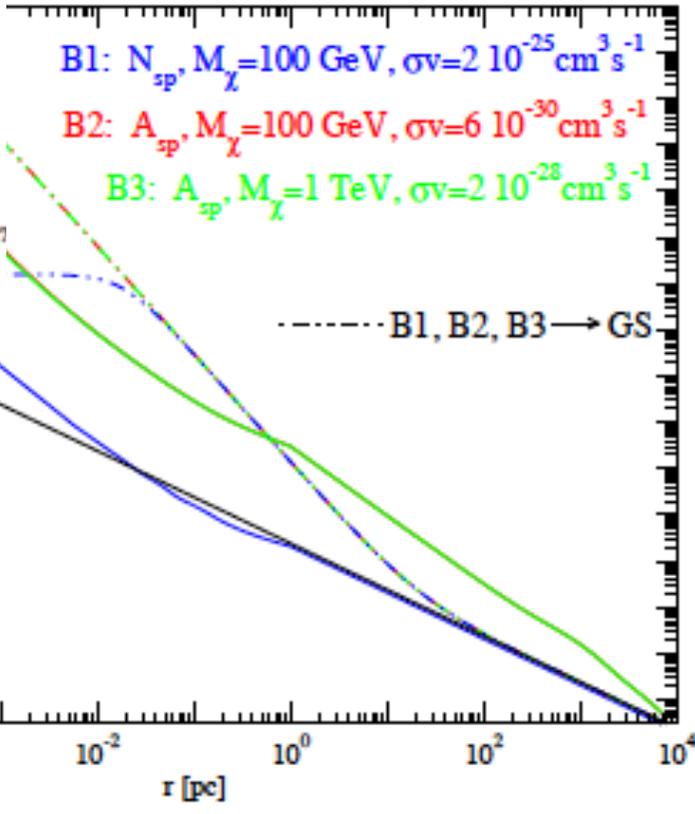

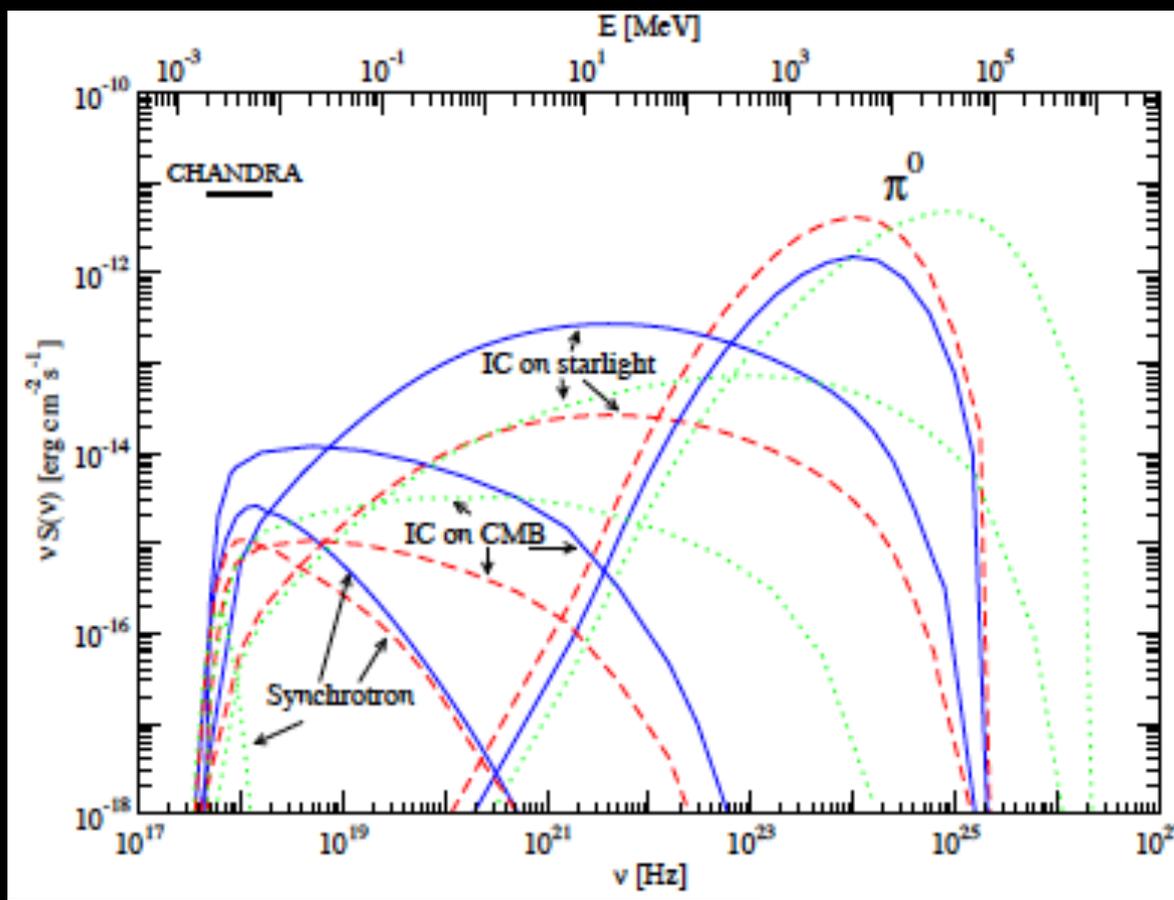

Fig. 2. HESS J1745–290 spectra derived with the combined Hillas/Model analysis for the whole H.E.S.S. GC dataset covering the three years 2004, 2005 and 2006. The shaded areas are the 1σ confidence intervals for the power law with an exponential cut-off fit (left) and the smoothed broken power law fit (right). The last points represent 95% confidence level upper limits on the flux. The fit residuals corresponding to the respective fits are shown on the lower panels.
