 - Abelian Higgs strings
 - Strings of various types and origins
 - Dynamics of infinitely thin strings
 - The simplest case: Nambu–Goto strings
 - Temporal gauge
 - String dynamics
 - Intercommutation of Abelian Higgs strings

Original motivations: topological defects

- Phase transitions in the early universe
 - ◆ Triggered by the spontaneous breakdown of the fundamental interactions [Kirzhnits:1972, Kobsarev:1974, Kibble:1976]

- Example: Abelian Higgs model and $U(1)$ symmetry

$$\mathcal{L}_h = \frac{1}{2} (D_\mu \Phi)^\dagger (D^\mu \Phi) - \frac{1}{4} H_{\mu\nu} H^{\mu\nu} - V(\Phi),$$

$$D_\mu = \partial_\mu + igB_\mu, \quad V(\Phi) = \frac{\lambda}{8} (|\Phi|^2 - \eta_v^2)^2 + \mathcal{O}(\Theta^2 |\Phi|^2)$$

$V[\Re(\Phi), \Im(\Phi)]$ at $\Theta > \Theta_c$

$$\Phi_0 = 0, \quad \delta\Phi_0 = 0$$

$V[\Re(\Phi), \Im(\Phi)]$ at $\Theta < \Theta_c$

$$\Phi_0 = \eta_v e^{i\theta}, \quad \delta\Phi_0 \neq 0$$

Theoretical aspects

❖ The simplest case:

Nambu-Goto strings

❖ Temporal gauge

❖ String dynamics

❖ Intercommutation of Abelian Higgs strings

Nambu-Goto simulations

Analytical models

Cosmological signatures

String non-Gaussianities with Planck

Perspectives and conclusion

Formation of topological defects

- Kibble–Zurek mechanism: $\ell_c < d_h$

- Conserved topological charge

$$\oint \frac{d\theta(s)}{ds} ds = 2\pi n$$

- Invariance group \mathcal{M} of the vacuum

For $\mathcal{G} \rightarrow \mathcal{H}$ and $\forall g \in \mathcal{G}$, one has

$$\mathcal{M} \equiv \{g\Phi_0 / \Phi_0 \in \mathcal{H}\} \sim \mathcal{G}/\mathcal{H}$$

- Homotopy groups and defects

$$\pi_0(\mathcal{M}) \approx \{I\} \implies \exists \text{ domain walls}$$

$$\pi_1(\mathcal{M}) \approx \{I\} \implies \exists \text{ cosmic strings}$$

$$\pi_2(\mathcal{M}) \approx \{I\} \implies \exists \text{ monopoles}$$

 - Nambu–Goto simulations
- Analytical models
- Cosmological signatures
 - String non-Gaussianities with Planck
- Perspectives and conclusion

Abelian Higgs strings

- Field profiles within a Nielsen-Olesen vortex

$$\Phi = \eta_v H(\varrho) e^{in\theta},$$

$$B_\mu = \frac{Q(\varrho) - n}{g} \delta_{\mu\theta}$$

with

$$m_h = \sqrt{\lambda} \eta_v, \quad m_b \equiv g \eta_v$$

- Stress tensor integrated over transverse directions

$$T^{tt} = -T^{zz} = \frac{\lambda \eta_v^4}{2} \left[(\partial_\varrho H)^2 + \frac{Q^2 H^2}{\varrho^2} + \frac{(H^2 - 1)^2}{4} + \frac{\lambda}{g^2} \frac{(\partial_\varrho Q)^2}{\varrho^2} \right]$$

$$\implies \text{energy density} = \text{string tension} \Leftrightarrow U = T = \mathcal{O}\left(\frac{m_h^2}{m_b^2}\right) \eta_v^2$$

String non-Gaussianities with Planck

Perspectives and conclusion

- Topological defects
 - ◆ Global strings [Davis:1985, Durrer:1998rw, Yamaguchi:1999yp]
 - ◆ Non-Abelian strings [Vilenkin:1984rt, Dvali:1993qp, Spergel:1996ai, Bucher:1998mh, McGraw:1998]
 - ◆ K- and DBI-strings [Babichev:2006cy, Babichev:2007tn, Sarangi:2007mj]
 - ◆ Current-carrying strings [Witten:1984eb, Davis:1988ip, Carter:1989dp, Peter:1992dw, Peter:1992ta]
- Line-like energy density distributions
 - ◆ Semi-local strings: energetically favoured for $m_b > m_h$ [Vachaspati:1991, Hindmarsh:1991jq, Achúcarro:1999it]
 - ◆ Cosmic superstrings: bound states made of p F -strings and q $D1$ -brane [Witten:1985fp, Copeland:2009ga, Sakellariadou:2008ie, Polchinski:2004ia, Davis:2008dj]
 - ◆ Nambu–Goto strings: Lorentz invariant two-dimensional worldsheet [Goto:1971ce, Nambu:1974]
- Carter strings [Carter:1989xk, Carter:1992vb, Carter:1994zs, Carter:2000wv]
 - ◆ Infinitely thin strings with an internal structure: $U \neq T$
 - ◆ Two-dimensional models of current carrying strings

Dynamics of infinitely thin strings

Theoretical aspects

- ❖ Original motivations: topological defects
- ❖ Formation of topological defects
- ❖ Abelian Higgs strings
- ❖ Strings of various types and origins

Dynamics of infinitely thin strings

- ❖ The simplest case: Nambu-Goto strings
- ❖ Temporal gauge
- ❖ String dynamics
- ❖ Intercommutation of Abelian Higgs strings

Nambu-Goto simulations

Analytical models

Cosmological signatures

String non-Gaussianities with Planck

Perspectives and conclusion

- String = two-dimensional worldsheet located at: $x^\mu = X^\mu(\xi^a)$

- ◆ Induced metric on the string: $\gamma_{ab} = g_{\mu\nu} \frac{\partial X^\mu}{\partial \xi^a} \frac{\partial X^\nu}{\partial \xi^b}$

- Carter's covariant formalism

- ◆ First fundamental form: projector onto the string worldsheet

$$q^{\mu\nu} \equiv \gamma^{ab} \frac{\partial X^\mu}{\partial \xi^a} \frac{\partial X^\nu}{\partial \xi^b} \implies \begin{cases} \perp^\mu{}_\nu \equiv g^\mu{}_\nu - q^\mu{}_\nu, \\ \bar{\nabla}_\mu \equiv q^\alpha{}_\mu \nabla_\alpha \\ K_{\mu\nu}{}^\rho \equiv q^\alpha{}_\nu \bar{\nabla}_\mu q^\rho{}_\alpha \end{cases}$$

- ◆ Stress tensor in its eigenvector basis: $u^2 = -1, v^2 = 1, u^\alpha v_\alpha = 0$

$$\begin{aligned} \bar{T}^{\mu\nu} &= U u^\mu u^\nu - T v^\mu v^\nu = (U - T) u^\mu u^\nu - T q^{\mu\nu}, \\ q^{\mu\nu} &= -u^\mu u^\nu + v^\mu v^\nu \end{aligned}$$

- ◆ For a barotropic equation of state $U = U(T)$

$$\bar{\nabla}_\rho \bar{T}^{\rho\sigma} = 0 \implies K^\rho = \perp^\rho{}_\sigma \left(\frac{U}{T} - 1 \right) u^\alpha \bar{\nabla}_\alpha u^\sigma$$

The simplest case: Nambu–Goto strings

- Lorentz invariance $\implies U = T \implies K^\mu = 0$

- ◆ Equations of motion

$$K^\mu = \frac{1}{\sqrt{-\gamma}} \partial_a (\sqrt{-\gamma} \gamma^{ab} \partial_b X^\mu) + \Gamma_{\nu\rho}^\mu \gamma^{ab} \partial_a X^\nu \partial_b X^\rho = 0$$

- ◆ Can also be directly obtained from: $\mathcal{S} = -U \int d^2\xi \sqrt{-\gamma}$

- In Friedmann–Lemaître background: $\tau \equiv \xi^0$ and $\sigma \equiv \xi^1$

- ◆ Transverse gauge: $g_{\mu\nu} \frac{\partial X^\mu}{\partial \tau} \frac{\partial X^\nu}{\partial \sigma} = \dot{X}^\mu \dot{X}_\mu = 0$

- ◆ Equation of motion: $\varepsilon \equiv \sqrt{-\frac{\dot{X}^2}{\dot{X}^2}}$

$$\ddot{X}^\mu + \left(\frac{\dot{\varepsilon}}{\varepsilon} + \frac{2}{a} \frac{da}{dX^0} \dot{X}^0 \right) \dot{X}^\mu - \frac{1}{\varepsilon} \left(\frac{\dot{X}^\mu}{\varepsilon} \right)' - \frac{2}{a} \frac{da}{dX^0} \frac{\dot{X}^0}{\varepsilon} \frac{\dot{X}^\mu}{\varepsilon} + \delta_0^\mu \frac{2}{a} \frac{da}{dX^0} \dot{X}^2 = 0$$

Theoretical aspects

- ◆ Original motivations: topological defects
- ◆ Formation of topological defects
- ◆ Abelian Higgs strings
- ◆ Strings of various types and origins
- ◆ Dynamics of infinitely thin strings

The simplest case: Nambu–Goto strings

- ◆ Temporal gauge
- ◆ String dynamics
- ◆ Intercommutation of Abelian Higgs strings

Nambu–Goto simulations

Analytical models

Cosmological signatures

String non-Gaussianities with Planck

Perspectives and conclusion

Temporal gauge

- Gauge fixing complete by identifying τ with the background time

$$\tau = X^0 = \eta \implies \begin{cases} \dot{\vec{X}} \cdot \dot{\vec{X}} = 0, & \varepsilon = \sqrt{\frac{\dot{\vec{X}}^2}{1 - \dot{\vec{X}}^2}}, & \dot{\varepsilon} + 2\mathcal{H}\varepsilon\dot{\vec{X}}^2 = 0, \\ \ddot{\vec{X}} + 2\mathcal{H}(1 - \dot{\vec{X}}^2) - \frac{1}{\varepsilon} \left(\frac{\dot{\vec{X}}}{\varepsilon}\right)' = 0 \end{cases}$$

- Bennet–Bouchet equivalent equations [Bouchet:1988,Bennett:1989,Bennett:1990]

- ◆ Lightcone-like coordinates: $u = \int \varepsilon d\sigma - \tau$ and $v = \int \varepsilon d\sigma + \tau$

- ◆ Left and right movers: $\vec{p}(\tau, u) \equiv \frac{\dot{\vec{X}}}{\varepsilon} - \dot{\vec{X}}$ and $\vec{q}(\tau, v) \equiv \frac{\dot{\vec{X}}}{\varepsilon} + \dot{\vec{X}}$

$$\frac{\partial \vec{p}}{\partial \tau} = -\mathcal{H} [\vec{q} - \vec{p}(\vec{p} \cdot \vec{q})], \quad \frac{\partial \vec{q}}{\partial \tau} = -\mathcal{H} [\vec{p} - \vec{q}(\vec{p} \cdot \vec{q})], \quad \frac{\dot{\varepsilon}}{\varepsilon} = -\mathcal{H} (1 - \vec{p} \cdot \vec{q})$$

Theoretical aspects

- ❖ The simplest case: Nambu–Goto strings

Temporal gauge

- ❖ String dynamics
- ❖ Intercommutation of Abelian Higgs strings

Nambu–Goto simulations

Analytical models

Cosmological signatures

String non-Gaussianities with Planck

Perspectives and conclusion

String dynamics

- Propagation of left- right-moving waves

- ◆ In Minkowski ($\mathcal{H} = 0$): $\dot{\vec{X}}(\tau, \sigma) = \frac{1}{2} [\vec{p}(\sigma + \tau) + \vec{q}(\sigma - \tau)]$

- ◆ In FLRW spacetime: damped and interactions on Hubble scales

- Interaction between strings is microphysics dependent

- ◆ Abelian Higgs strings with $m_h \simeq m_b$: $P \simeq 1$ and formation of 2 kinks

- ◆ Cosmic superstrings: $P \ll 1$ (presence of extra-dimensions)

- ◆ (p, q) -strings: charge conservation \implies Y-junctions, kinematic constraints and kinks proliferation [Copeland:2007nv, Bevis:2009az, Binetruy:2010bq,

Steer:2013nea]

- ❖ Loop distribution in scaling

Analytical models

Cosmological signatures

String non-Gaussianities with Planck

Perspectives and conclusion

Nambu–Goto simulations

- Goal: getting realistic statistics of string networks in FLRW
 - ◆ Only one parameter : U
 - ◆ Nambu–Goto networks are already complex: non-linear and non-local properties
- Method: solve numerically the string evolution in FLRW
 - ◆ From some representative initial conditions [Vachaspati:1984]
 - ◆ IC are mostly irrelevant due to the existence of a cosmological attractor [Bennett:1989,Allen:1990,Albrecht:1989,Ringeval:2005kr,Vanchurin:2005pa]
- Numerical parameters

Comoving box size = 1
Initial correlation length $\ell_c = 1/100$
Initial resolution length $\ell_r = 1/2000$

Theoretical aspects

Nambu–Goto simulations

- ◆ A small matter era run (movie)
- ◆ Cosmological attractor
- ◆ Scaling of the energy density
- ◆ Relaxation towards scaling
- ◆ Loop distribution in scaling

Analytical models

Cosmological signatures

String non-Gaussianities with Planck

Perspectives and conclusion

A small matter era run (movie)

Cosmic Strings Simulation in *FLRW* Spacetime

Cosmological attractor

- Long strings ($\ell > d_h$) rapidly reach a scaling evolution

- ◆ Energy density evolves as radiation/matter ($\propto 1/d_h^2$) instead of naively expected $\rho \propto 1/a^2$

$$\rho_\infty \frac{d_h^2}{U} \Big|_{\text{mat}} = 28.4 \pm 0.9 \quad \rho_\infty \frac{d_h^2}{U} \Big|_{\text{rad}} = 37.8 \pm 1.7$$

- ◆ Kibble mechanism: formation of loops that transfer some energy to sub-horizon length scales

- A similar mechanism happens to loops themselves due to their self-intersections

$$\text{With } \alpha \equiv \frac{\ell}{d_h}, \quad \frac{d\rho_o}{d\alpha} = \mathcal{S}(\alpha) \frac{U}{d_h^2} \quad \Longrightarrow \quad \frac{dn}{d\alpha} = \frac{\mathcal{S}(\alpha)}{\alpha d_h^3}$$

- ◆ The scaling function $\mathcal{S}(\alpha)$ can be determined from simulations
- ◆ But only for $\alpha_c < \alpha < 1$ where α_c involves physical effects not accounted in the Nambu–Goto model

Theoretical aspects

Nambu–Goto simulations

◆ A small matter era run (movie)

◆ Cosmological attractor

◆ Scaling of the energy density

◆ Relaxation towards scaling

◆ Loop distribution in scaling

Analytical models

Cosmological signatures

String non-Gaussianities with Planck

Perspectives and conclusion

Scaling of the energy density

● Scaling of the energy densities for loops and long strings

[Ringeval:2005kr, Blanco-Pillado:2013qja]

Theoretical aspects

Nambu-Goto simulations

❖ A small matter era run (movie)

❖ Cosmological attractor

❖ Scaling of the energy density

❖ Relaxation towards scaling

❖ Loop distribution in scaling

Analytical models

Cosmological signatures

String non-Gaussianities with Planck

Perspectives and conclusion

$$\rho_\infty \frac{d_h^2}{U} \Big|_{\text{mat}} = 28.4 \pm 0.9$$

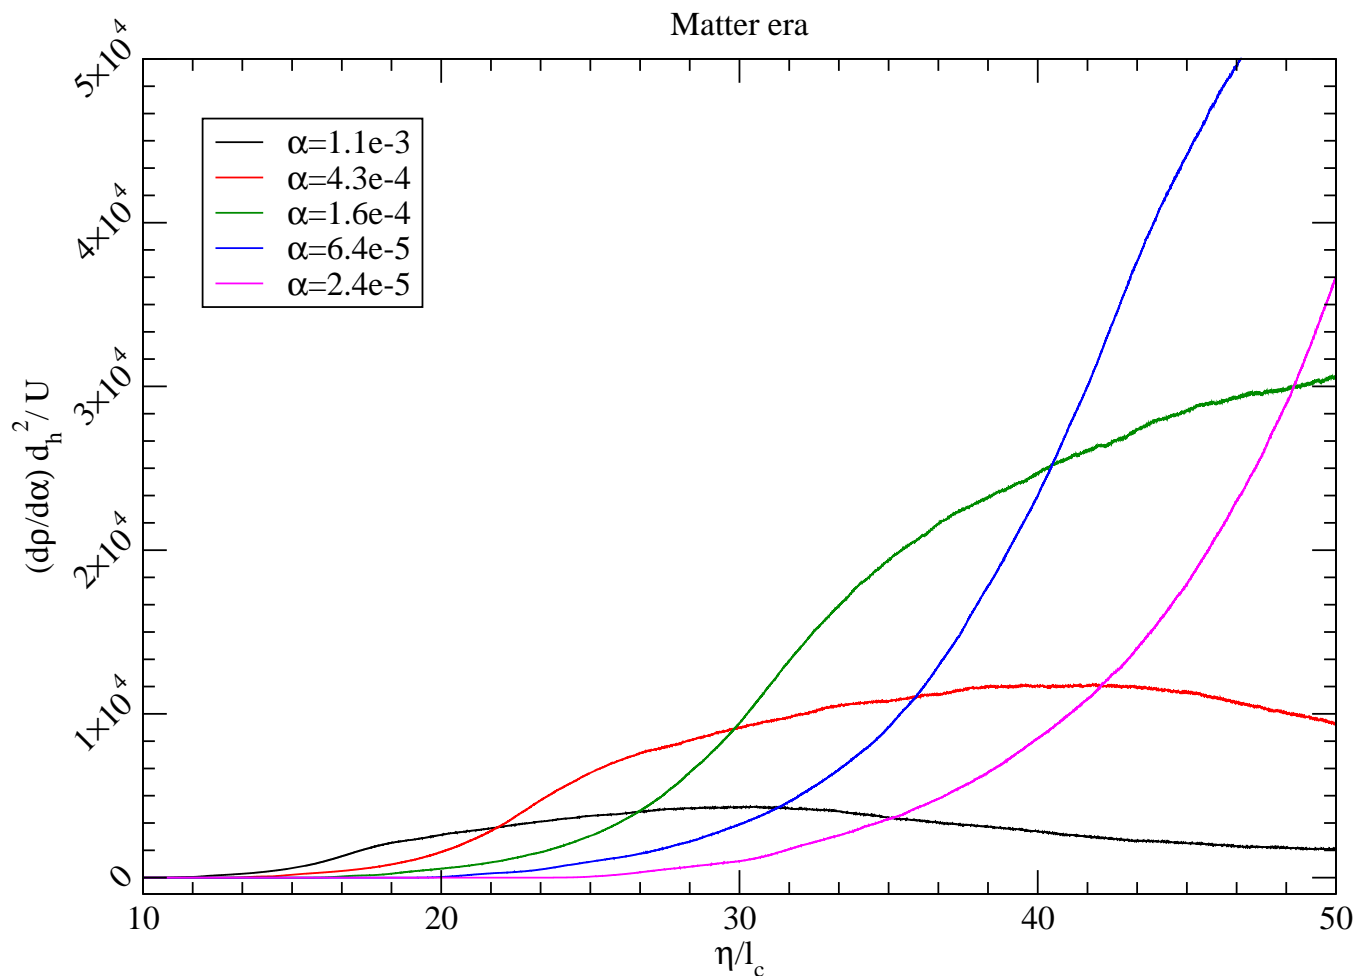

$$\rho_\infty \frac{d_h^2}{U} \Big|_{\text{rad}} = 37.8 \pm 1.7$$

$$d\rho_\circ \times \frac{d_h^2}{U} = \mathcal{S}(\alpha) \quad (\text{time independent})$$

Relaxation towards scaling

- Transient effects last longer for smaller loops

- NG simulations do not incorporate GW \Rightarrow do not describe $\alpha < \alpha_c$

Theoretical aspects

Nambu-Goto simulations

- ❖ A small matter era run (movie)

- ❖ Cosmological attractor

- ❖ Scaling of the energy density

- ❖ Relaxation towards scaling

- ❖ Loop distribution in scaling

Analytical models

Cosmological signatures

String non-Gaussianities with Planck

Perspectives and conclusion

Loop distribution in scaling

- By the end of the run

Theoretical aspects

Nambu–Goto simulations

- ❖ A small matter era run (movie)
- ❖ Cosmological attractor
- ❖ Scaling of the energy density
- ❖ Relaxation towards scaling

Loop distribution in scaling

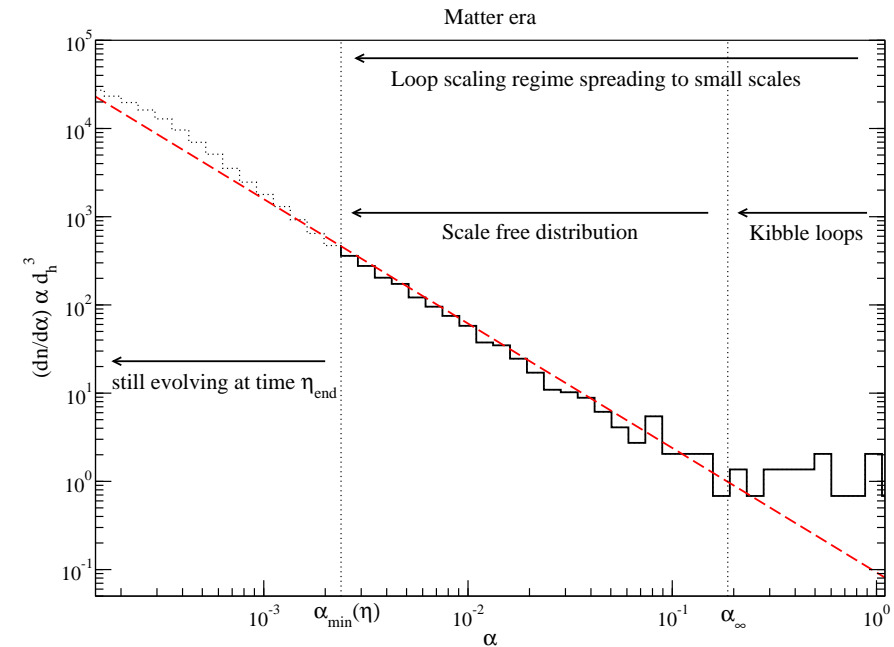

Analytical models

Cosmological signatures

String non-Gaussianities with Planck

Perspectives and conclusion

Scaling parts

- Scaling form $\mathcal{S}(\alpha) = \frac{C_o}{\alpha^p}$ with

$$\begin{cases} p & = & 1.41^{+0.08}_{-0.07} \\ C_o & = & 0.09^{-0.03}_{+0.03} \end{cases} \text{ mat}$$

$$\text{and } \begin{cases} p & = & 1.60^{+0.21}_{-0.15} \\ C_o & = & 0.21^{-0.12}_{+0.13} \end{cases} \text{ rad}$$

Loop distribution in scaling

- By the end of the run

Theoretical aspects

Nambu–Goto simulations

- ❖ A small matter era run (movie)
- ❖ Cosmological attractor
- ❖ Scaling of the energy density
- ❖ Relaxation towards scaling

Loop distribution in scaling

Analytical models

Cosmological signatures

String non-Gaussianities with Planck

Perspectives and conclusion

Non-scaling parts

Scaling parts

- Scaling form $\mathcal{S}(\alpha) = \frac{C_o}{\alpha^p}$ with

$$\begin{cases} p & = & 1.41 & ^{+0.08} \\ & & & ^{-0.07} \\ C_o & = & 0.09 & ^{-0.03} \\ & & & ^{+0.03} \end{cases} \quad \text{mat}$$

$$\text{and} \quad \begin{cases} p & = & 1.60 & ^{+0.21} \\ & & & ^{-0.15} \\ C_o & = & 0.21 & ^{-0.12} \\ & & & ^{+0.13} \end{cases} \quad \text{rad}$$

Theoretical aspects

Nambu–Goto simulations

Analytical models

- ❖ Polchinsky-Rocha model

- ❖ Inclusion of gravitational backreaction
- ❖ Cosmological loop distribution
- ❖ Relaxation effects are accounted
- ❖ Some numerical values
- ❖ Extension to vortons

Cosmological signatures

String non-Gaussianities with Planck

Perspectives and conclusion

Polchinsky-Rocha model

- No fragmentation, no reconnection, loops from long string only

[Polchinski:2006ee, Dubath:2007mf, Rocha:2007ni]

- ◆ Predicts a power law scaling function

$$\mathcal{S}(\alpha) \propto \alpha^{2\chi-2} \implies p = 2(1 - \chi)$$

- ◆ Parameter χ can be inferred from the long string scaling

- From Martins & Shellard simulations, they independently found

$$p_{\text{mat}} \simeq 1.5, \quad p_{\text{rad}} \simeq 1.8$$

- In the PR model χ is related to two-point functions [Hindmarsh:2008dw]

$$\langle \dot{X}^A(\sigma) \dot{X}^B(\sigma') \rangle = \frac{1}{2} \delta^{AB} T(\sigma - \sigma') \quad T(\sigma) \simeq \bar{t}^2 - c_1 \left(\frac{\sigma}{\hat{\xi}} \right)^{2\chi}$$

- Agreement with simulations suggests that all neglected effects mostly renormalise C_o

Theoretical aspects

Nambu-Goto simulations

Analytical models

◆ Polchinsky-Rocha model

◆ Inclusion of gravitational backreaction

◆ Cosmological loop distribution

◆ Relaxation effects are accounted

◆ Some numerical values

◆ Extension to vortons

Cosmological signatures

String non-Gaussianities with Planck

Perspectives and conclusion

Including loop's gravitational radiation

- Boltzmann equation + PR production function

- ◆ PR loop production function (from string shape correlations)

$$t^5 \mathcal{P}(\ell, t) = c \left(\frac{\ell}{t} \right)^{2\chi-3}$$

- ◆ In an expanding universe

$$\frac{d}{dt} \left(a^3 \frac{dn}{d\ell} \right) = a^3 \mathcal{P}(\ell, t)$$

- ◆ A loop shrinks due to G.W. emission ($\gamma \equiv \ell/t$) [Allen:1992]

$$\frac{d\ell}{dt} = -\gamma_d \simeq 100GU$$

- Evolution equation [Rocha:2007ni]

$$\frac{\partial}{\partial t} \left(a^3 \frac{dn}{d\ell} \right) - \gamma_d \frac{\partial}{\partial \ell} \left(a^3 \frac{dn}{d\ell} \right) = a^3 \mathcal{P}(\ell, t)$$

Theoretical aspects

Nambu-Goto simulations

Analytical models

◆ Polchinsky-Rocha model

◆ Inclusion of gravitational backreaction

◆ Cosmological loop distribution

◆ Relaxation effects are accounted

◆ Some numerical values

◆ Extension to vortons

Cosmological signatures

String non-Gaussianities with Planck

Perspectives and conclusion

Inclusion of gravitational backreaction

- PR model + GW emission + GW backreaction [Lorenz:2010sm]
 - ◆ Allows us to extrapolate numerical simulations to small ℓ
 - ◆ Boltzmann equation ($\gamma_d = \Gamma GU$)

$$\frac{\partial}{\partial t} \left(a^3 \frac{dn}{d\ell} \right) - \gamma_d \frac{\partial}{\partial \ell} \left(a^3 \frac{dn}{d\ell} \right) = a^3 \mathcal{P}(\ell, t).$$

- ◆ Postulated piecewise scaling loop production function

$$t^5 \mathcal{P} \left(\gamma = \frac{\ell}{t}, t \right) \propto \gamma^{2\chi-3}$$
$$\gamma_c \ll \gamma_d \ll \gamma_\infty \lesssim 1$$

Cosmological loop distribution

- Can be completely solved analytically (see arXiv.1006.0931)

- From any initial loop distribution $\mathcal{N}_{\text{ini}}(\ell)$, one gets $\mathcal{F}(\gamma, t) \equiv \frac{\partial n}{\partial \ell}(\gamma, t)$

$$t^4 \mathcal{F}(\gamma \geq \gamma_c, t) = \left(\frac{t}{t_{\text{ini}}}\right)^4 \left(\frac{a_{\text{ini}}}{a}\right)^3 t_{\text{ini}}^4 \mathcal{N}_{\text{ini}}\left\{\left[\gamma + \gamma_d \left(1 - \frac{t_{\text{ini}}}{t}\right)\right] t\right\} + C(\gamma + \gamma_d)^{2\chi-3} f\left(\frac{\gamma_d}{\gamma + \gamma_d}\right) - C(\gamma + \gamma_d)^{2\chi-3} \left(\frac{t}{t_{\text{ini}}}\right)^{2\chi+1} \left(\frac{a_{\text{ini}}}{a}\right)^3 f\left(\frac{\gamma_d}{\gamma + \gamma_d} \frac{t_{\text{ini}}}{t}\right),$$

$$t^4 \mathcal{F}(\gamma_\tau \leq \gamma < \gamma_c, t) = \left(\frac{t}{t_{\text{ini}}}\right)^4 \left(\frac{a_{\text{ini}}}{a}\right)^3 t_{\text{ini}}^4 \mathcal{N}_{\text{ini}}\left\{\left[\gamma + \gamma_d \left(1 - \frac{t_{\text{ini}}}{t}\right)\right] t\right\} + C_c(\gamma + \gamma_d)^{2\chi_c-3} f_c\left(\frac{\gamma_d}{\gamma + \gamma_d}\right) - C(\gamma + \gamma_d)^{2\chi-3} \left(\frac{t}{t_{\text{ini}}}\right)^{2\chi+1} \left(\frac{a_{\text{ini}}}{a}\right)^3 f\left(\frac{\gamma_d}{\gamma + \gamma_d} \frac{t_{\text{ini}}}{t}\right)$$

$$+ K \left(\frac{\gamma_c + \gamma_d}{\gamma + \gamma_d}\right)^4 \left[\frac{a\left(\frac{\gamma + \gamma_d}{\gamma_c + \gamma_d} t\right)}{a(t)}\right]^3,$$

$$t^4 \mathcal{F}(0 < \gamma < \gamma_\tau, t) = \left(\frac{t}{t_{\text{ini}}}\right)^4 \left(\frac{a_{\text{ini}}}{a}\right)^3 t_{\text{ini}}^4 \mathcal{N}_{\text{ini}}\left\{\left[\gamma + \gamma_d \left(1 - \frac{t_{\text{ini}}}{t}\right)\right] t\right\} + C_c(\gamma + \gamma_d)^{2\chi_c-3} f_c\left(\frac{\gamma_d}{\gamma + \gamma_d}\right)$$

$$\gamma_\tau(t) \equiv (\gamma_c + \gamma_d) \frac{t_{\text{ini}}}{t} - \gamma_d, \quad \mu \equiv 3\nu - 2\chi - 1$$

$$f(x) \equiv {}_2F_1(3 - 2\chi, \mu; \mu + 1; x) \quad f_c(x) \equiv {}_2F_1(3 - 2\chi_c, \mu_c; \mu_c + 1; x)$$

Perspectives and conclusion

Relaxation effects are accounted

- Example: transition radiation–matter

Theoretical aspects

Nambu–Goto simulations

Analytical models

❖ Polchinsky–Rocha model

❖ Inclusion of gravitational backreaction

❖ Cosmological loop distribution

❖ Relaxation effects are accounted

❖ Some numerical values

❖ Extension to vortons

Cosmological signatures

String non-Gaussianities with Planck

Perspectives and conclusion

Some numerical values

- Density parameter of cosmic string loops (assuming $\gamma_c \ll \gamma_d \ll 1$)

$$\left. \begin{aligned} \rho_o &= \frac{U}{t^2} \int_0^3 t^4 \mathcal{F}(\gamma, t) \gamma d\gamma \\ C &\equiv C_o (1 - \nu)^{3-p}, \quad \chi = 1 - \frac{p}{2} \end{aligned} \right\} \Rightarrow \Omega_o = \frac{3\pi^2 C}{(1 - \chi) \sin(2\pi\chi)} \frac{GU}{\gamma_d^{1-2\chi}}$$

- ◆ With NG typical values and $\gamma_d \simeq 100GU$ ($\gamma_d t_0 < 380$ kpc)

$$\Omega_o \simeq 0.10(GU)^{0.59} < 10^{-5} \quad (\text{with current CMB bounds on } GU)$$

- Number density of cosmic strings loops in a box of size L (today)

$$t^3 n_L = \int_0^{L/t} t^4 \mathcal{F}(\gamma, t) d\gamma \simeq \frac{C}{\gamma_d \gamma_c^{1-2\chi}}$$

- ◆ From PR model [Polchinski:2007rg]: $\gamma_c \simeq 10(GU)^{1+2\chi}$ ($\gamma_c t_0 < 8$ pc)

$$t^3 n_L \simeq 6.1 \times 10^{-5} (GU)^{-1.65} > 5.5 \times 10^{-6} \text{ Mpc}^{-3}$$

Theoretical aspects

Nambu-Goto simulations

Analytical models

◆ Polchinsky-Rocha model

◆ Inclusion of gravitational backreaction

◆ Cosmological loop distribution

◆ Relaxation effects are accounted

◆ Some numerical values

◆ Extension to vortons

Cosmological signatures

String non-Gaussianities with Planck

Perspectives and conclusion

Extension to vortons

- Boltzmann equation for current carrying loops [Peter:2013jj]: $n(\ell, t, N)$

$$\frac{\partial}{\partial t} \left[a^3 \mathcal{J}(\ell, t) \frac{\partial^2 n}{\partial \ell \partial N} \right] - \left[\gamma_d \Theta \left(\ell - \frac{N}{\sqrt{U}} \right) + \gamma_v \Theta \left(\frac{N}{\sqrt{U}} - \ell \right) \right] \frac{\partial}{\partial \ell} \left[a^3 \mathcal{J}(\ell, t) \frac{\partial^2 n}{\partial \ell \partial N} \right] = a^3 \mathcal{J}(\ell, t) \mathcal{P}(\ell, t) \delta \left(N - \sqrt{\frac{\ell}{\lambda}} \right)$$

- Again exactly solvable for any $\mathcal{N}_{\text{ini}}(\ell)$ (see arXiv:1302.0953)

- ❖ Compatible with small angle simulated maps

String non-Gaussianities with Planck

Perspectives and conclusion

Power spectrum of string induced anisotropies

- External source of cosmological perturbations: $\mathcal{D}\mathcal{X} = \mathcal{S}$ [Durrer:1997ep, Bevis:2006mj, Urrestilla:2007sf,]

$$\langle \mathcal{X}^\dagger(\eta_0, k) \mathcal{X}(\eta_0, k) \rangle \propto \iint^{\eta_0} G_k^\dagger(\eta') G_k(\eta) \langle \mathcal{S}^\dagger(\eta', k) \mathcal{S}(\eta, k) \rangle d\eta d\eta'$$

- Abelian string simulations [Bevis:2010gj]

$$\langle \mathcal{S}^\dagger \mathcal{S} \rangle \propto \frac{1}{\sqrt{\eta\eta'}} f_{\mu\nu\rho\sigma} \left(k\sqrt{\eta\eta'}, \frac{\eta}{\eta'} \right)$$

- Planck + WP + ACTSPT + BICEP2 [Lizarraga:2014xza]
- Fraction (at $\ell = 10$) $\leq 2\%$
- Tension $GU \leq 3 \times 10^{-7}$
- Dominate at $\ell > 3000$?

❖ Isoscele triangle configurations

❖ Compatible with small angle simulated maps

String non-Gaussianities with Planck

Perspectives and conclusion

String-induced CMB distortions

- Nambu–Goto strings ($U = T$): no static gravitational effects
- Do have General Relativity effects on light and thus on CMB (Gott-Kaiser-Stebbins)

- ISW from Nambu–Goto stress tensor + Einstein equations: [Hindmarsh 94, Stebbins 95]

$$\Theta(\hat{n}) \equiv \frac{\delta T}{T_{\text{CMB}}} = -4GU \int_{\mathbf{X} \cap \mathbf{x}_\gamma} \left[\mathbf{u}(\hat{n}) \cdot \frac{\mathbf{X}_\perp}{X_\perp^2} \right] \left(1 + \hat{n} \cdot \dot{\mathbf{X}} \right) d\sigma$$

$$\mathbf{u} = \dot{\mathbf{X}} - \frac{(\hat{n} \cdot \mathbf{X}') \cdot \mathbf{X}'}{1 + \hat{n} \cdot \dot{\mathbf{X}}} \quad \mathbf{X}_\perp \equiv X\hat{n} - \mathbf{X}$$

- At small angular scales, in 2D transverse Fourier space ($\mathbf{k} \cdot \hat{n} \simeq 0$):

$$\Theta \simeq \frac{8\pi i GU}{l^2} \int_{\mathbf{X} \cap \mathbf{x}_\gamma} (\mathbf{u} \cdot \mathbf{l}) e^{-i\mathbf{l} \cdot \mathbf{X}} d\sigma$$

Theoretical aspects

❖ Bispectrum of string induced CMB anisotropies

❖ Bispectrum comes from expansion

❖ Isoscele triangle configurations

❖ Compatible with small angle simulated maps

String non-Gaussianities with Planck

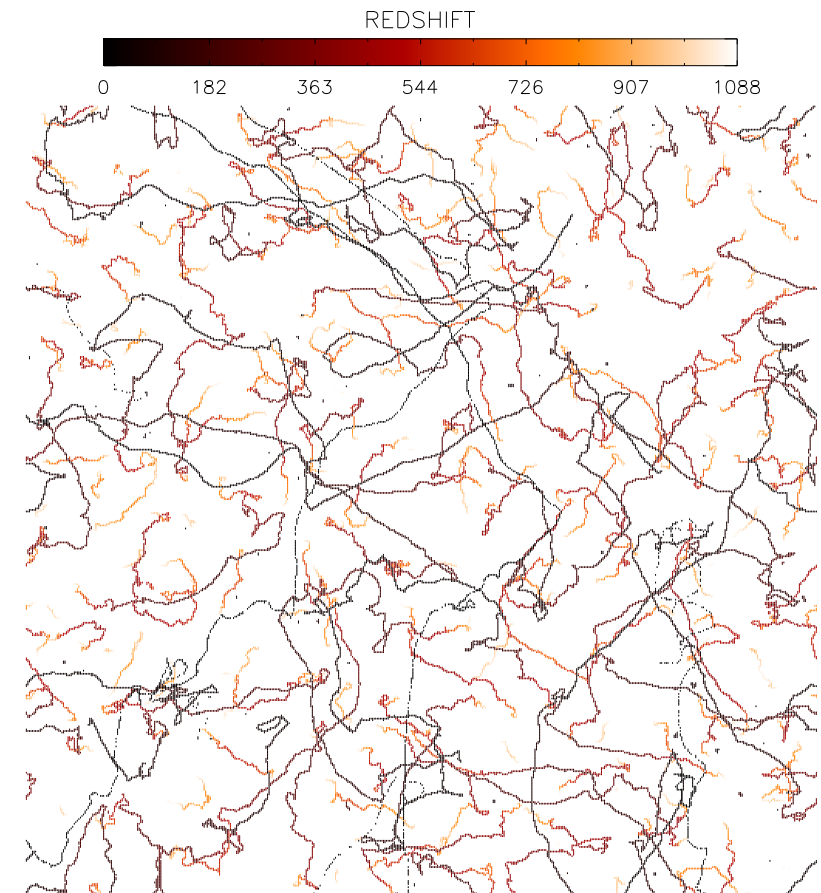

Perspectives and conclusion

Systematics from loops not in scaling

- Maps with no loops or with all loops

no loops

all structures, including IC effects

- Mostly renormalize the amplitude by at most a few percents

Theoretical aspects

Nambu–Goto simulations

Analytical models

Cosmological signatures

- ❖ Power spectrum of string induced anisotropies
- ❖ String induced CMB distortions
- ❖ Small angles and flat sky limit

Systematics from loops not in scaling

- ❖ String effects since last scattering
- ❖ Basic non-Gaussian estimators
- ❖ Observable string correlators
- ❖ Bispectrum of string induced CMB anisotropies
- ❖ Bispectrum comes from expansion
- ❖ Isoscele triangle configurations
- ❖ Compatible with small angle simulated maps

String non-Gaussianities with Planck

Perspectives and conclusion

String effects since last scattering

- ISW from strings explains the power spectrum at the large multipoles

- Amplitude at $\ell = 1000$: $\ell(\ell + 1) C_\ell / (2\pi) \simeq 14 (GU)^2$

◆ Compatible with Abelian Higgs power spectrum

- Variance: $\sigma^2 \simeq (150.7 \pm 18) (GU)^2$

- Power law behaviour at small scales

$$\ell(\ell + 1) C_\ell \underset{\ell \gg 1}{\propto} \ell^{-p} \quad \text{with} \quad p = 0.889^{+0.001}_{-0.090}$$

❖ Basic non-Gaussian estimators

❖ Observable string correlators

❖ Bispectrum of string induced CMB anisotropies

❖ Bispectrum comes from expansion

❖ Isoscele triangle configurations

❖ Compatible with small angle simulated maps

String non-Gaussianities with Planck

Perspectives and conclusion

Basic non-Gaussian estimators

● Gradient magnitude

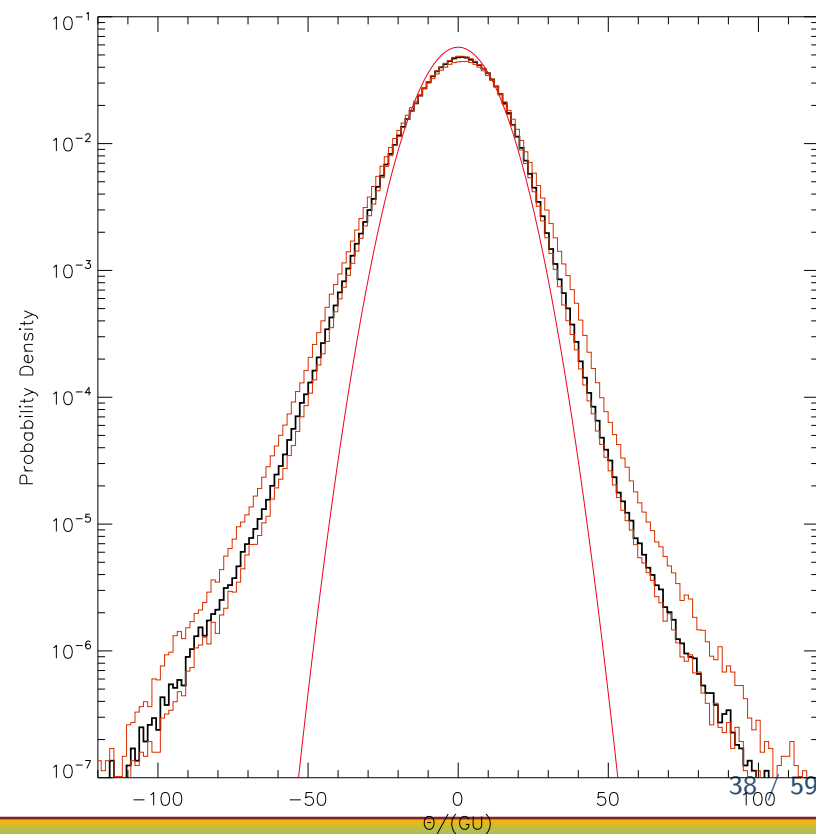

$$|\nabla\Theta| \equiv \sqrt{\left(\frac{d\Theta}{d\alpha}\right)^2 + \left(\frac{d\Theta}{d\beta}\right)^2}$$

● One-point functions

$$g_1 \equiv \left\langle \frac{(\Theta - \bar{\Theta})^3}{\sigma^3} \right\rangle \simeq -0.22 \pm 0.12$$

$$g_2 \equiv \left\langle \frac{(\Theta - \bar{\Theta})^4}{\sigma^4} \right\rangle - 3 \simeq 0.69 \pm 0.29.$$

❖ Observable string correlators

❖ Bispectrum of string induced CMB anisotropies

❖ Bispectrum comes from expansion

❖ Isoscele triangle configurations

❖ Compatible with small angle simulated maps

String non-Gaussianities with Planck

Perspectives and conclusion

Not enough for detection?

- Experimental beam damps the signal: PLANCK 217 GHz
 - ◆ One-point function is nearly Gaussian, up to the rare events.
 - ◆ Gradient magnitude is sensitive to all: inf + SZ + stgs

Theoretical aspects

Nambu-Goto simulations

Analytical models

Cosmological signatures

- ◆ Power spectrum of string induced anisotropies
- ◆ String-induced CMB distortions
- ◆ Small angles and flat sky limit
- ◆ Systematics from loops not in scaling

Basic non-Gaussian estimators

- ◆ Observable string correlators
- ◆ Bispectrum of string induced CMB anisotropies
- ◆ Bispectrum comes from expansion
- ◆ Isoscele triangle configurations
- ◆ Compatible with small angle simulated maps

String non-Gaussianities with Planck

Perspectives and conclusion

Three-point function of the CMB anisotropies

- Non-vanishing skewness \Rightarrow 3-pts function $\neq 0$

$$\langle \hat{\Theta}_{\mathbf{k}_1} \hat{\Theta}_{\mathbf{k}_2} \hat{\Theta}_{\mathbf{k}_3} \rangle = B(\mathbf{k}_1, \mathbf{k}_2, \mathbf{k}_3) (2\pi)^2 \delta(\mathbf{k}_1 + \mathbf{k}_2 + \mathbf{k}_3)$$

- From ISW, can be evaluated analytically at small angle

[Hindmarsh:2009qk, Ringeval:2010ca]

- ◆ Calculation easier in the light cone gauge (instead of temporal)

$$\tau = X^0 + X^3 \implies \mathbf{u} = \dot{\mathbf{X}}$$

$$B(\mathbf{k}_1, \mathbf{k}_2, \mathbf{k}_3) = i\epsilon^3 \frac{1}{\mathcal{A}} \frac{k_{1A} k_{2B} k_{3C}}{k_1^2 k_2^2 k_3^2} \int d\sigma_1 d\sigma_2 d\sigma_3 \langle \dot{X}_1^A \dot{X}_2^B \dot{X}_3^C e^{i\delta^{ab} \mathbf{k}_a \cdot \mathbf{X}_b} \rangle$$

with $\dot{X}_a^A = \dot{X}^A(\sigma_a)$, $a, b \in \{1, 2, 3\}$, $\epsilon = 8\pi G U$

- Assuming $\dot{\mathbf{X}}$ and $\dot{\mathbf{X}}$ are Gaussian random variables

$$\langle C^{ABC} e^{iD} \rangle = i \langle C^{ABC} D \rangle e^{-\langle D^2 \rangle / 2}$$

Theoretical aspects

Nambu-Goto simulations

Analytical models

Cosmological signatures

◆ Power spectrum of string induced anisotropies

◆ Observable string correlators

◆ Bispectrum of string induced CMB anisotropies

◆ Bispectrum comes from expansion

◆ Isoscele triangle configurations

◆ Compatible with small angle simulated maps

String non-Gaussianities with Planck

Perspectives and conclusion

Observable string correlators

- Expand everything in terms of two-point correlators

$$\langle C^{ABC} D \rangle = \frac{1}{4} \delta^{AB} [k_1^C \Pi(\sigma_{13}) + k_2^C \Pi(\sigma_{23})] V(\sigma_{12}) + \text{c.c.}$$

$$\langle D^2 \rangle = -\frac{1}{2} [\mathbf{k}_1 \cdot \mathbf{k}_3 \Gamma(\sigma_{13}) + \mathbf{k}_2 \cdot \mathbf{k}_3 \Gamma(\sigma_{23}) + \mathbf{k}_1 \cdot \mathbf{k}_2 \Gamma(\sigma_{12})]$$

$$\Gamma(\sigma - \sigma') \equiv \langle [\mathbf{X}(\sigma) - \mathbf{X}(\sigma')]^2 \rangle = \int_{\sigma'}^{\sigma} d\sigma_1 \int_{\sigma'}^{\sigma} d\sigma_2 T(\sigma_1 - \sigma_2)$$

$$\Pi(\sigma - \sigma') \equiv \langle [\mathbf{X}(\sigma) - \mathbf{X}(\sigma')] \cdot \dot{\mathbf{X}}(\sigma') \rangle = \int_{\sigma'}^{\sigma} d\sigma_1 M(\sigma_1 - \sigma')$$

- Depend on three functions

$$\langle \dot{X}^A(\sigma) \dot{X}^B(\sigma') \rangle = \frac{1}{2} \delta^{AB} V(\sigma - \sigma')$$

$$\langle \dot{X}^A(\sigma) \dot{X}^B(\sigma') \rangle = \frac{1}{2} \delta^{AB} M(\sigma - \sigma')$$

$$\langle \dot{X}^A(\sigma) \dot{X}^B(\sigma') \rangle = \frac{1}{2} \delta^{AB} T(\sigma - \sigma')$$

❖ Observable string correlators

❖ Bispectrum of string induced CMB anisotropies

❖ Bispectrum comes from expansion

❖ Isoscele triangle configurations

❖ Compatible with small angle simulated maps

String non-Gaussianities with Planck

Perspectives and conclusion

Bispectrum of string induced CMB anisotropies

- Integration can be done at large wavenumbers: $\kappa_{ab} \equiv \mathbf{k}_a \cdot \mathbf{k}_b \gg 1$

$$B(\mathbf{k}_1, \mathbf{k}_2, \mathbf{k}_3) = -\epsilon^3 \pi c_0 \frac{\bar{v}^2}{\bar{t}^4} \frac{L\hat{\xi}}{\mathcal{A}} \frac{1}{\hat{\xi}^2} \frac{1}{k_1^2 k_2^2 k_3^2} \left[\frac{k_1^4 \kappa_{23} + k_2^4 \kappa_{31} + k_3^4 \kappa_{12}}{(\kappa_{23} \kappa_{31} + \kappa_{12} \kappa_{31} + \kappa_{12} \kappa_{23})^{3/2}} \right]$$

- Sensitive to the (averaged projected) small scales $\sigma \rightarrow 0$ [Hindmarsh:1995]

$$V(\sigma) \sim \bar{v}^2, \quad \Gamma(\sigma) \sim \bar{t}^2 \sigma^2, \quad \Pi(\sigma) \sim \frac{1}{2} \frac{c_0}{\hat{\xi}} \sigma^2 \quad [\hat{\xi} \equiv \Gamma'(\infty)]$$

❖ Observable string correlators

❖ Bispectrum of string induced CMB anisotropies

❖ Bispectrum comes from expansion

❖ Isoscele triangle configurations

❖ Compatible with small angle simulated maps

String non-Gaussianities with Planck

Perspectives and conclusion

Bispectrum comes from expansion

- Proportional to $c_0 \equiv \hat{\xi} \langle \ddot{\mathbf{X}} \cdot \dot{\mathbf{X}} \rangle \neq 0$?

- ◆ Light cone gauge + FLRW + $\dot{\mathbf{X}}, \dot{\mathbf{X}}$ Gaussian random variables

$$\langle \ddot{\mathbf{X}} \cdot \dot{\mathbf{X}} \rangle = \bar{\mathcal{H}} \left(\langle \dot{\mathbf{X}}^2 \rangle \langle \dot{\mathbf{X}}^2 \rangle - \langle \dot{\mathbf{X}} \cdot \dot{\mathbf{X}} \rangle^2 \right) = \bar{\mathcal{H}} \bar{v}^2 \bar{t}^2$$

- ◆ For $\bar{\mathcal{H}} > 0 \Rightarrow c_0 > 0$: breaking of time reversal invariance

- String bispectrum exists only in an expanding universe

- ◆ Gives a negative skewness by integration

- ◆ Decays as a power law at small scales

- ◆ This is the CMB temperature bispectrum (what you see!)

- As opposed to primordial (f_{NL})

Theoretical aspects

Nambu–Goto simulations

◆ Bispectrum of string induced CMB anisotropies

◆ Bispectrum comes from expansion

◆ Isoscele triangle configurations

◆ Compatible with small angle simulated maps

String non-Gaussianities with Planck

Perspectives and conclusion

Isoscele triangle configurations

- Wavenumbers such that $k_1 = k_2 = k$ and $k_3 = 2k \sin(\theta/2)$

$$B_{\ell\ell\theta}(k, \theta) = -\epsilon^3 \pi c_0 \frac{\bar{v}^2}{\bar{t}^4} \frac{L\hat{\xi}}{\mathcal{A}} \frac{1}{\hat{\xi}^2 k^6} \frac{1 + 4 \cos \theta \sin^2(\theta/2)}{\sin^3 \theta}$$

- Amplified on elongated triangles; \pm at $\theta_0 = 2 \arccos \frac{\sqrt{3 - \sqrt{3}}}{2}$

◆ Filling the transparent universe with strings

◆ Massively parallel ray tracing method

◆ After a million of cpu-hours

◆ Comparison between flat and full sky

◆ Non-Gaussian searches for cosmic strings

Perspectives and conclusion

Massively parallel ray tracing method

- Sky pixelized with 200 000 000 lines of sight (4 times Planck maps)
 - ◆ Each direction receives cumulative contributions from all CS
 - ◆ Account for roughly 10^{17} iterations
- Parallelization implementation
 - ◆ MPI over the 3072 boxes + reduction
 - ◆ OpenMP over the 200 000 000 pixels
 - ◆ Vectorization of the most inner loop (string segments)
- Code development performed on the CP3-cosmo cluster (100 cores)
- Reasonable computing time demands a 100 TeraFlops computer :-/
 - ◆ The Planck collaboration has a few... (thanks to J. Borrill) :)

❖ After a million of cpu-hours

❖ Comparison between flat and full sky

❖ Non-Gaussian searches for cosmic strings

Perspectives and conclusion

Non-Gaussian searches for cosmic strings

● Full sky bispectrum [Ade:2013vla]

◆ Different methods used

- Modal bispectrum
- Wavelets
- Minkowski functionals

● Planck constraints on cosmic strings non-Gaussianities

$$f_{\text{NL}}^{\text{strg}} = 0.30 \pm 0.21 \Rightarrow GU < 8.8 \times 10^{-7}$$

$$\text{Real space} \Rightarrow GU < 7.8 \times 10^{-7}$$

- Very robust (ISW only) but slightly weaker than power spectrum bounds $GU < 1.3 \times 10^{-7} \rightarrow 3.2 \times 10^{-7}$

Four-point function of the CMB anistropies

- Same method as for the bispectrum with new features [Hindmarsh:2009es]

$$\left\langle \hat{\Theta}_{\mathbf{k}_1} \hat{\Theta}_{\mathbf{k}_2} \hat{\Theta}_{\mathbf{k}_3} \hat{\Theta}_{\mathbf{k}_4} \right\rangle = T(\mathbf{k}_1, \mathbf{k}_2, \mathbf{k}_3, \mathbf{k}_4) (2\pi)^2 \delta(\mathbf{k}_1 + \mathbf{k}_2 + \mathbf{k}_3 + \mathbf{k}_4)$$

$$T_{1234} = \frac{\epsilon^4}{\mathcal{A}} \frac{k_{1A} k_{2B} k_{3C} k_{4D}}{k_1^2 k_2^2 k_3^2 k_4^2} \int d\sigma_1 d\sigma_2 d\sigma_3 d\sigma_4 \left\langle \dot{X}_1^A \dot{X}_2^B \dot{X}_3^C \dot{X}_4^D e^{i\delta^{ab} \mathbf{k}_a \cdot \mathbf{X}_b} \right\rangle$$

- Flat directions: sensitive to **higher order in the correlators**

$$\text{Polchinski-Rocha model} \Rightarrow T(\sigma) \simeq \bar{t}^2 - c_1 \left(\frac{\sigma}{\xi} \right)^{2\chi}$$

- Trispectrum sensitives to the string microstructure!
 - ◆ $0 < \chi < 1, c_1 > 0$
 - ◆ NG: power-law exponent of the loop distribution
 - ◆ Other strings: related to the mean square velocity

Theoretical aspects

Nambu-Goto simulations

Analytical models

Cosmological signatures

String non-Gaussianities with Planck

Perspectives and conclusion

◆ Four-point function of the CMB anistropies

◆ Loops and CMB trispectrum

◆ Example: kite quadrilaterals

◆ Conclusion

Loops and CMB trispectrum

Theoretical aspects

Nambu-Goto simulations

Analytical models

Cosmological signatures

String non-Gaussianities with Planck

Perspectives and conclusion

❖ Four-point function of the CMB anisotropies

❖ Loops and CMB trispectrum

❖ Example: kite quadrilaterals

❖ Conclusion

- CMB trispectrum from strings is sensitive to $\langle \dot{X}^A(\sigma) \dot{X}^B(\sigma') \rangle$

$$T_\infty(\mathbf{k}_1, \mathbf{k}_2, \mathbf{k}_3, \mathbf{k}_4) \simeq \epsilon^4 \frac{\bar{v}^4}{\bar{t}^2} \frac{L \hat{\xi}}{\mathcal{A}} \left(c_1 \hat{\xi}^2 \right)^{-1/(2\chi+2)} f(\chi) g(\mathbf{k}_1, \mathbf{k}_2, \mathbf{k}_3, \mathbf{k}_4)$$

$$f(\chi) = \frac{\pi}{\chi+1} \Gamma\left(\frac{1}{2\chi+2}\right) [4(2\chi+1)(\chi+1)]^{1/(2\chi+2)}$$

- Geometrical factor scales as k^ρ : $\rho = 6 + 1/(1 + \chi)$

$$g(\mathbf{k}_1, \mathbf{k}_2, \mathbf{k}_3, \mathbf{k}_4) = \frac{\kappa_{12}\kappa_{34} + \kappa_{13}\kappa_{24} + \kappa_{14}\kappa_{23}}{k_1^2 k_2^2 k_3^2 k_4^2} [Y^2]^{-1/(2\chi+2)}$$

$$Y^2(\mathbf{k}_1, \mathbf{k}_2, \mathbf{k}_3, \mathbf{k}_4) \equiv -\kappa_{12} (k_3^2 k_4^2 - \kappa_{34}^2)^{\chi+1} + \text{cyclic},$$

- This is a consistency relation for loops production mechanism

Example: kite quadrilaterals

- Geometrical factor for kites: boost on elongated

$$g(\mathbf{k}_1, \mathbf{k}_2, \mathbf{k}_3, \mathbf{k}_4) = \frac{\cos^2(\alpha) [1 - 2 \cos(2\alpha) \cos(\theta)]}{\sin^2(\theta/2)} \frac{1}{k^\rho y^{2/(2+2\chi)}(\theta, \alpha)}$$

$$\rho = 6 + \frac{1}{1 + \chi}$$

- Bump for parallelograms at $\theta = \pi - 2\alpha$ ($Y^2 = 0$)

Theoretical aspects

Nambu-Goto simulations

Analytical models

Cosmological signatures

String non-Gaussianities with Planck

Perspectives and conclusion

◆ Four-point function of the CMB anisotropies

◆ Loops and CMB trispectrum

◆ Example: kite quadrilaterals

◆ Conclusion

Conclusion

- Currently: no string non-Gaussianities $\implies GU < 7.8 \times 10^{-7}$
- Future improvements
 - ◆ Searching for string induced trispectrum \implies window on their nature (trispectrum)
 - ◆ Next Planck data release + polarization + small scales experiments (BB [Seljak 06])
- Other observables than CMB: signal $\propto (GU)^{2,3,4}$
 - ◆ Galaxy surveys
 - ◆ GW direct detection (strongly dependent on the loop distribution)
 - ◆ 21 cm
- Detecting strings would give a lower bound on the energy scale of inflation!
