The network will observe the GWs in the high-frequency band

\[ 10 \text{ Hz} \lesssim f \lesssim 10^3 \text{ Hz} \]
Space-based laser interferometric detector

eLISA

eLISA will observe the GWs in the low-frequency band

\[ 10^{-4} \text{ Hz} \lesssim f \lesssim 10^{-1} \text{ Hz} \]
The inspiral and merger of compact binaries

Neutron stars spiral and coalesce

1. Neutron star \((M = 1.4 \, M_\odot)\) events will be detected by ground-based detectors LIGO/VIRGO

2. Stellar size black hole \((5 \, M_\odot \lesssim M \lesssim 20 \, M_\odot)\) events will also be detected by ground-based detectors

3. Supermassive black hole \((10^5 \, M_\odot \lesssim M \lesssim 10^8 \, M_\odot)\) events will be detected by the space-based detector eLISA

Black holes spiral and coalesce
Extreme mass ratio inspirals (EMRI) for eLISA

- A neutron star or a stellar black hole follows a highly relativistic orbit around a supermassive black hole. The gravitational waves generated by the orbital motion are computed using black hole perturbation theory.

- Observations of EMRIs will permit to test the no-hair theorem for black holes, i.e. to verify that the central black hole is described by the Kerr geometry.

PN theory vs BH perturbations

Rencontres de Moriond 11 / 29
3.5PN energy flux of compact binaries (4.5PN?)

[Blanchet, Faye, Iyer & Joguet 2002]

\[
\mathcal{F}^{GW} = -\frac{32c^5}{5G}\nu^2 x^5 \left\{ 1 + \left( -\frac{1247}{336} - \frac{35}{12}\nu \right) x + 4\pi x^{3/2} \right\} \\
+ \left( -\frac{44711}{9072} + \frac{9271}{504}\nu + \frac{65}{18}\nu^2 \right) x^2 + \left[ \cdots \right] x^{5/2} \\
+ \left[ \cdots \right] x^3 + \left[ \cdots \right] x^{7/2} + \left[ \cdots \right] x^4 + \left[ \cdots \right] x^{9/2} + \mathcal{O}(x^5) \right\}
\]

The orbital frequency and phase for quasi-circular orbits are deduced from an energy balance argument

\[
\frac{dE}{dt} = -\mathcal{F}^{GW}
\]

Spin contributions are also known to high order [Bohé, Marsat, Faye & Blanchet 2013]
General problem of the gravitational perturbation

- A particle is moving on a background space-time
- Its own stress-energy tensor modifies the background gravitational field
- Because of the “back-reaction” the motion of the particle deviates from a background geodesic hence the appearance of a gravitational self force (GSF)

The self acceleration of the particle is proportional to its mass

\[
\frac{D\tilde{u}^{\mu}}{d\tau} = f^{\mu} = O \left( \frac{m_1}{m_2} \right)
\]

- The self force is computed by numerical methods [Sago, Barack & Detweiler 2008]
Common regime of validity of GSF and PN

\[ \log_{10}\left(\frac{r}{m}\right) \]

\[ \log_{10}\left(\frac{m_2}{m_1}\right) \]

Luc Blanchet (IAP)

PN theory vs BH perturbations

Rencontres de Moriond
Both the PN and GSF approaches use a self-field regularization for point particles followed by a renormalization. However, the prescription are very different

1. GSF theory is based on a prescription for the Green function $G_R$ that is at once regular and causal [Detweiler & Whiting 2003]
2. PN theory uses **dimensional regularization** and it was shown that subtle issues appear at the 3PN order due to the appearance of poles $\propto (d - 3)^{-1}$

How can we make a meaningful comparison?

1. Restrict attention to the **conservative part** (circular orbits) of the dynamics
2. Find a **gauge-invariant observable** computable in both formalisms
Circular orbit means Helical Killing symmetry.
Looking at the conservative part of the dynamics

Physical situation
no incoming radiation condition

Situation with the HKV
standing waves at infinity
For exactly circular orbits the geometry admits a helical Killing vector with

\[ K^\mu \partial_\mu = \partial_t + \Omega \partial_\varphi \quad (\text{asymptotically}) \]

The four-velocity of the particle is necessarily tangent to the Killing vector hence

\[ K_1^\mu = z_1 u_1^\mu \]

This \( z_1 \) is the Killing energy of the particle associated with the HKV and is also a redshift

The relation \( z_1(\Omega) \) is well-defined in both PN and SF approaches and is gauge-invariant
Post-Newtonian calculation of the redshift factor

In a coordinate system such that $K^\mu \partial_\mu = \partial_t + \Omega \partial_\varphi$ everywhere this invariant quantity reduces to the zero-th component of the particle’s four-velocity,

\[
 u^t_1 = \frac{1}{z_1} = \left( - (g_{\mu\nu})_1 \frac{v_1^\mu v_1^\nu}{c^2} \right)^{-1/2}
\]

regularized metric

One needs a self-field regularization
- Hadamard regularization will yield an ambiguity at 3PN order
- **Dimensional regularization** will be free of any ambiguity at 3PN order
The redshift factor of particle 1 through 3PN order and augmented by 4PN and 5PN logarithmic terms is

$$u_t^1 = 1 + \left( \frac{3}{4} \sqrt{1 - 4\nu} - \frac{\nu}{2} \right) x + \left( \ldots + \left[ \ldots \right] \nu \ln x \right) x^5 + \left( \ldots + \left[ \ldots \right] \nu \ln x \right) x^6 + O(x^7)$$

where we pose $\nu = m_1 m_2 / m^2$ and $x = (Gm\Omega / c^3)^{3/2}$

The logarithms are due to the (conservative part of) radiation reaction tails
High-order PN result for the redshift factor

[Blanchet, Detweiler, Le Tiec & Whiting 2010ab]

- We re-expand in the small mass-ratio limit \( q = m_1/m_2 \ll 1 \) so that

\[
  u^t = u^t_{\text{Schw}} + q u^t_{\text{SF}} + q^2 u^t_{\text{PSF}} + \mathcal{O}(q^3)
\]

- Posing \( y = \left( \frac{G m_2 \Omega}{c^3} \right)^{3/2} \) we find

\[
  u^t_{\text{SF}} = -y - 2y^2 - 5y^3 + \left( -\frac{121}{3} + \frac{41}{32} \pi^2 \right) y^4 + \left( a_4 - \frac{64}{5} \ln y \right) y^5 + \left( a_5 - \frac{956}{105} \ln y \right) y^6 + \mathcal{O}(y^7)
\]

\[
  \begin{align*}
  &\text{3PN} \\
  &\text{4PN} \\
  &\text{5PN}
  \end{align*}
\]
The 3PN prediction agrees with the GSF value with 7 significant digits:

<table>

High-order PN fit to the numerical self-force
[Blanchet, Detweiler, Le Tiec & Whiting 2010ab]
More recent developments

1. 4PN coefficient also known analytically [Bini & Damour 2013]

\[ a_{4\text{PN}} = -\frac{1157}{15} + \frac{677}{512} \pi^2 - \frac{256}{5} \ln 2 - \frac{128}{5} \gamma_E \]

and agrees with previous numerical value [Le Tiec, Blanchet & Whiting 2012]

2. Super-high precision analytical and numerical GSF calculations of the redshift factor up to 10PN order [Shah, Friedman & Whiting 2013]

Analytically known GSF terms [Shah, Friedman & Whiting 2014]

In addition to super-high precision numerical high-order terms we have

\[ u_{\text{SF}}^t = -y - 2y^2 - 5y^3 + \left( -\frac{121}{3} + \frac{41}{32} \pi^2 \right) y^4 \]

\[ + \left( -\frac{1157}{15} + \frac{677}{512} \pi^2 - \frac{128}{5} \gamma_E - \frac{64}{5} \ln(16y) \right) y^5 \]

\[ - \frac{956}{105} y^6 \ln y - \frac{13696 \pi}{525} y^{13/2} - \frac{51256}{567} y^7 \ln y + \frac{81077 \pi}{3675} y^{15/2} \]

\[ + \frac{27392}{525} y^8 \ln^2 y + \frac{82561159 \pi}{467775} y^{17/2} - \frac{27016}{2205} y^9 \ln^2 y \]

\[ - \frac{11723776 \pi}{55125} y^{19/2} \ln y - \frac{4027582708}{9823275} y^{10} \ln^2 y \]

\[ + \frac{99186502 \pi}{1157625} y^{21/2} \ln y + \frac{23447552}{165375} y^{11} \ln^3 y + \cdots \]

Notice the occurrence of half-integral PN terms starting at 5.5PN order.
Half-integral conservative PN terms (of type $\frac{n}{2}$PN) that are instantaneous are in fact zero for circular orbits:

$$(z_1)_{\text{inst}} \sim \sum_{j,k,p,q} \nu^j \left( \frac{Gm}{rc^2} \right)^k \left( \frac{v^2}{c^2} \right)^p \left( \frac{n \cdot v}{c} \right)^q$$

They come from hereditary-type (non-local-in-time) integrals and their first occurrence is due to tail-of-tail multipole interactions

$$M \times M \times M_{ij}$$

arising precisely at the 5.5PN order.
We have to solve many d’Alembertian equations of the type

$$\Box h \sim \sum \frac{G^3 M^2}{c^n r^k} \int_1^\infty dx \, Q_m(x) \, M^{(a)}_L(t - rx/c)$$

The solution in the near-zone \(r \to 0\) reads [Blanchet 1993]

$$h \sim \partial \left\{ \frac{G(t - r/c) - G(t + r/c)}{r} \right\} + \Box_{\text{inst}}^{-1} S$$

where \(G(u) \sim \sum \frac{G^3 M^2}{c^n} \int_0^\infty d\tau \ln \tau \, M^{(a)}_L(u - \tau)\)

Only the homogeneous solution contribute to half-integral PN terms
Split the dynamics into conservative and dissipative pieces and keep only the conservative part (neglecting readiation reaction dissipative effects)

$$G_{\text{cons}}(u) \sim \sum \frac{G^3 M^2}{c^n} \int_0^\infty d\tau \frac{M_L^{(a)}(u-\tau) + M_L^{(a)}(u+\tau)}{2}$$

symmetric-in-time integral

With that prescription one checks that the equations of motion are indeed conservative, i.e. that the acceleration is purely radial.

The final result for the redshift factor is in full agreement with analytical and numerical GSF computations

\[
\begin{align*}
\alpha_{5.5\text{PN}} &= -\frac{13696}{525}\pi, \\
\alpha_{6.5\text{PN}} &= \frac{81077}{3675}\pi, \\
\alpha_{7.5\text{PN}} &= \frac{82561159}{467775}\pi
\end{align*}
\]
Conclusions

1. Compact binary star systems are the most important source for gravitational wave detectors LIGO/VIRGO and eLISA

2. Post-Newtonian theory has proved to be the appropriate tool for describing the inspiral phase of compact binaries up to the ISCO

3. For massive BH binaries the PN templates should be matched to the results of numerical relativity for the merger and ringdown phases

4. The PN approximation is now tested against different approaches such as the perturbative GSF and performs extremely well
