Concluding
Remarks

Analogously to Gordon's paper¹, we study specific geometries such that the metric and its inverse assume a binomial form

$$\hat{q}_{\mu\nu} = A\eta_{\mu\nu} + B\Phi_{\mu\nu}, \quad \hat{q}^{\mu\nu} = \alpha\eta^{\mu\nu} + \beta\Phi^{\mu\nu}, \quad (1)$$

where A , B , α and β are functions, $\eta^{\mu\nu}$ is the Minkowski metric and $\Phi^{\mu\nu}$ is a symmetric tensor satisfying

$$\Phi_{\mu\nu}\Phi^{\nu\lambda} = m\delta_{\mu}^{\lambda} + n\Phi_{\mu}^{\lambda}. \quad (2)$$

Note that m and n are not completely arbitrary functions.

¹W. Gordon, *Ann. Phys. (Leipzig)* **72** 421 (1923).

Examples:

- Scalar fields: $\Phi_{\mu\nu} = \partial_\mu\phi\partial_\nu\phi$;
- Electromagnetic fields: $\Phi_{\mu\nu} = F_\mu{}^\alpha F_{\alpha\nu}$;
- Spinor fields: $\Phi_{\mu\nu} = (\mathbf{J}_\mu + \epsilon\mathbf{I}_\mu)(\mathbf{J}_\nu + \epsilon\mathbf{I}_\nu)$.

We analyze each case in details afterwards.

Geodesic motion condition

The Dynamical Bridges also present interesting results in the kinematics, as follows:

Theorem

Let Γ be a congruence of curves represented by the vector field V_μ in a given space-time. This vector follows along a geodesic in the metric $\hat{q}_{\mu\nu}$, if the condition below is satisfied²

$$\frac{1}{2}\hat{N}_{,\mu} + V_{[\mu,\nu]}\hat{q}^{\nu\alpha}V_\alpha - p(\lambda)V_\mu = 0,$$

where \hat{N} is the norm of V_μ calculated with $\hat{q}_{\mu\nu}$ and $p(\lambda)$ is a function of the affine parameter λ .

Electromagnetic DB: Born-Infeld³

Consider the Born-Infeld Lagrangian

$$L = \beta^2 \left(1 - \sqrt{\hat{U}} \right), \quad (5)$$

where $\hat{U} \equiv 1 + \hat{F}/(2\beta^2) - \hat{G}^2/(16\beta^4)$, defined in

$$\hat{e}^{\mu\nu} \equiv a\eta^{\mu\nu} + b\Phi^{\mu\nu} \quad \text{and} \quad \Phi_{\mu\nu} \equiv F_{\mu\alpha} F^{\alpha}_{\nu} \quad (6)$$

where $\hat{F} \equiv F_{\mu\nu} F_{\alpha\beta} \hat{e}^{\mu\alpha} \hat{e}^{\nu\beta}$ and $\hat{G} \equiv F_{\mu\nu} F^*_{\alpha\beta} \hat{e}^{\mu\alpha} \hat{e}^{\nu\beta}$.

The dynamical equations are

$$\frac{1}{\sqrt{-\hat{e}}} \partial_\nu \left[\frac{\sqrt{-\hat{e}}}{\hat{U}} \left(\hat{F}^{\mu\nu} - \frac{1}{4\beta^2} \hat{G} \hat{F}^{*\mu\nu} \right) \right] = 0. \quad (7)$$

Concluding
Remarks

Consider the Maxwell Lagrangian

$$L = -\frac{1}{4}F \quad (8)$$

where $F \equiv F_{\mu\nu} F_{\alpha\beta} \eta^{\mu\alpha} \eta^{\nu\beta}$ defined in Minkowski space $\eta_{\mu\nu}$.
The dynamical equations are

$$\frac{1}{\sqrt{-\eta}} \partial_\nu (\sqrt{-\eta} F^{\mu\nu}) = 0. \quad (9)$$

To demonstrate this equivalence is necessary to know how $\hat{F}^{\mu\nu}$ and its dual are related to the Maxwell's fields. In this case, the correspondence is

$$\begin{cases} n - \epsilon F m + \frac{\hat{G}}{2\beta^2} \epsilon m & = -\frac{Q}{4}, \\ -\epsilon G m + \frac{\hat{G} n}{2\beta^2} & = 0, \end{cases} \quad (10)$$

where $\epsilon \equiv b/a$ and

$$n = 1 + \frac{\epsilon^2 G^2}{16}, \quad m = 1 - \frac{\epsilon F}{4}, \quad Q = 1 - \frac{\epsilon F}{2} - \frac{\epsilon^2 G^2}{16}.$$

Vector Fields
Spinor Fields
Scalar Fields

Concluding
Remarks

In the curved space, the dynamics of Ψ is

$$i\hbar c \hat{\gamma}^\mu \hat{\nabla}_\mu \Psi - mc^2 \Psi = 0, \quad (13)$$

and $\hat{\nabla}_\mu \equiv \partial_\mu - \hat{\Gamma}_\mu^{FI} - \hat{V}_\mu$, where \hat{V}_μ is an arbitrary element of the algebra given by

$$\hat{V}_\mu = i \frac{mc}{\hbar} \frac{F_{\mu\nu}}{\beta} \hat{\gamma}^\nu \gamma_5. \quad (14)$$

This gives $\hat{\nabla}_\mu \hat{\gamma}^\nu = [\hat{V}_\mu, \hat{\gamma}^\nu]$, but maintains $\hat{\nabla}_\alpha \hat{e}^{\mu\nu} = 0$ and preserves the current $\hat{\nabla}_\mu \hat{J}^\mu = 0$.

Using Eqs. for $\hat{e}_{\mu\nu}$, $\hat{\gamma}^\mu$ and \hat{V}_μ , we obtain the following equation for Ψ in Minkowski space

$$i \hbar c \gamma^\mu \partial_\mu \Psi + \frac{m c^2}{2\beta} F_{\mu\nu} [\gamma^\mu, \gamma^\nu] \gamma_5 \Psi - m c^2 \Psi = 0. \quad (15)$$

This equation provides a magnetic moment for Ψ , whose the intensity is

$$\mu^G = \frac{m c^2}{\beta}. \quad (16)$$

We named this contribution as *geometric magnetic moment*.

Geometric magnetic moment for charged particles

Dynamical

Theorem

Polynomial Metrics

Applications

Dynamical
Context

Vector Fields

Spinor Fields

Scalar Fields

Concluding
Remarks

Charged particles have a classical source for μ . For electrons, it is the Bohr magneton $\mu_B = e \hbar / 2m_e$. Then, the total value of the electron magnetic moment should be read as

$$\mu_e = \mu_B + \frac{m_e c^2}{\beta} + \text{quantum corrections.}$$

The first term is classical, the second one is the geometric magnetic moment and then we have quantum corrections (due to the charge).

Comparison with experiments

Vector Fields
Spinor Fields
Scalar Fields

Concluding
Remarks

Anomalous magnetic moment: the value a_l of the anomaly of the magnetic moment μ_l of the particle l is defined as

$$a_l = \frac{g_l - 2}{2} = \frac{m_l}{m_e} \frac{\mu_l}{\mu_B} - 1, \quad (17)$$

where $l = (e, \mu, \tau)$, g_l is the Landé factor and m_l is the mass⁴.

Data: there are measurements of the anomaly for e^- (the most precise) and for μ (test the entire SM). For τ , it is unobservable due to its short mean-life ($\sim 2.9 \times 10^{-13}$ s).

⁴Data from the *Particle Data Group* (2013).

μ -case

The difference Δa between the experimental and theoretical value of the anomaly for muons gives the upper limit in which μ^G can contribute. So, if the effects of $\hat{e}^{\mu\nu}$ appear at this order, we have

$$\mu_{\mu}^G \doteq \Delta a_{\mu} \frac{e\hbar}{2m_{\mu}}. \quad (18)$$

On the other hand, the formula is given by

$$\mu_{\mu}^G = \frac{m_{\mu}c^2}{\beta}. \quad (19)$$

Assuming that μ_{μ}^G correspond to the remaining anomaly of muon, then we can estimate the critical field:

$$\beta \approx 1.31 \times 10^{23} T.$$

Vector Fields

Spinor Fields

Scalar Fields

Concluding
Remarks

Assuming this value for β , the geometric corrections for the electron are

$$\mu_e^G = 6.74 \times 10^{-14} \mu_B. \quad (20)$$

The difference between theory and experiments is

$$\Delta a_e = -0.40 \times 10^{-12}. \quad (21)$$

We can see that they are compatible with the effects of $\hat{e}^{\mu\nu}$.

It is expected that μ_ν and its quantum corrections are zero. However, the extended SM suggests $\mu_\nu \neq 0$ and $\mu_\nu \propto m_\nu$. Then, it seems natural to propose that μ_ν has only the geometrical origin. In this case,

$$\mu_\nu = \frac{m_\nu c^2}{\beta} = 1.32 \times 10^{-19} \mu_B. \quad (22)$$

This value is in agreement with⁵ phenomenology and close to the ESM value ($3, 2 \times 10^{-19} \mu_B$).

Dynamical
Bridges

Eduardo
Bittencourt

Introduction

Kinematical
Context

Theorem
Polynomial Metrics
Applications

Dynamical
Context

Vector Fields
Spinor Fields
Scalar Fields

Concluding
Remarks

The corresponding dynamics in Minkowski space is a generalization of a Nambu-Jona-Lasinio (NJL) model

$$i\gamma^\mu \nabla \Psi_R + i\dot{\beta}(A + iB\gamma_5)\Phi_L = 0, \tag{25}$$

$$i\gamma^\mu \nabla \Psi_L = 0,$$

where $A \equiv \bar{\Psi}\Psi$ and $B \equiv i\bar{\Psi}\gamma_5\Psi$.

Further comments:

- There is an exact solution given by the Inomata condition $\partial_\mu \Psi = -(1/2)\dot{\beta}H_\mu \Psi$.
- For massive fermions, we expected that the self-interacting term should be negligible compared to the mass.
- Main drawback: J^μ is not conserved in flat space for the right-handed component. Possibly, a conformal transformation in Eq. (24) can solve the problem.

Formulation of the GSG

Dynamical
Bridges

Eduardo
Bittencourt

Introduction

Kinematical
Context

Theorem

Polynomial Metrics

Applications

Dynamical
Context

Vector Fields

Spinor Fields

Scalar Fields

Concluding
Remarks

Let us summarize the main properties of the GSG⁷:

- The gravity is described by Φ which satisfies a nonlinear dynamics;
- The theory satisfies the principle of general covariance and minimal coupling;
- All kinds of matter and energy interact with Φ only through

$$q^{\mu\nu} = \alpha\eta^{\mu\nu} + \beta\frac{\partial^\mu\Phi\partial^\nu\Phi}{w},$$

i.e., gravity is a **geometrical phenomenon**;

- Test particles follow geodesics relative to $q^{\mu\nu}$;
- Φ is nontrivially related to Φ_N ;

Static and spherically symmetric solution

Dynamical
Bridges

Eduardo
Bittencourt

Introduction

Kinematical
Context

Theorem
Polynomial Metrics
Applications

Dynamical
Context

Vector Fields
Spinor Fields
Scalar Fields

Concluding
Remarks

Let us start with flat background

$$ds_M^2 = dt^2 - \alpha \left(\frac{1}{2\alpha} \frac{d\alpha}{dr} r + 1 \right)^2 dr^2 - \alpha r^2 d\Omega^2, \quad (27)$$

where r is related to the radial coordinate R through $R = \sqrt{\alpha(r)} r$. The static and spherical symmetry suggests $\Phi = \Phi(r)$. Therefore, the gravitational metric becomes

$$ds^2 = \frac{1}{\alpha} dt^2 - B dr^2 - r^2 d\Omega^2, \quad (28)$$

where $B \equiv \frac{\alpha}{\alpha + \beta} \left(\frac{1}{2\alpha} \frac{d\alpha}{dr} r + 1 \right)^2$ and $\alpha = e^{-2\Phi}$.

By successive approximations, we obtained an *Ansatz* for V , as follows:

$$V(\Phi) = \frac{(e^\Phi - 3e^{3\Phi})^2}{4} \quad (29)$$

and then, the solution of the field equation yields

$$\Phi = \frac{1}{2} \ln \left(1 - \frac{r_H}{r} \right), \quad (30)$$

where $r_H \equiv 2MG/c^2$. Now, the line element can be written down as

$$ds^2 = \left(1 - \frac{r_H}{r} \right) dt^2 - \left(1 - \frac{r_H}{r} \right)^{-1} dr^2 - r^2 d\Omega^2. \quad (31)$$

Note that GSG reproduces solar system tests with a good approximation.

Dynamics in the presence of matter

Dynamical
Bridges

Eduardo
Bittencourt

Introduction

Kinematical
Context

Theorem
Polynomial Metrics
Applications

Dynamical
Context

Vector Fields
Spinor Fields
Scalar Fields

Concluding
Remarks

We start with the action for Φ written in the Minkowski metric. Then, we use the DB to rewrite it in $q^{\mu\nu}$ as

$$\delta S_M = -2 \int \sqrt{-q} d^4x \sqrt{V} \square \Phi \delta \Phi. \quad (32)$$

Then, we add the matter content L_m and make the variation wrt $q^{\mu\nu}$ and obtain the usual conserved $T_{\mu\nu}$. As $q_{\mu\nu}$ is not the fundamental quantity and we must rewrite $\delta q_{\mu\nu}$ as function of $\delta \Phi$.

After some calculation, we get

$$\sqrt{V} \square \Phi = \kappa \chi, \quad (33)$$

where the quantity χ involves a nontrivial coupling between $\nabla_{\mu} \Phi$ and $T_{\mu\nu}$. The Newtonian limit of the theory is obtained by fixing $\kappa \equiv 8\pi G/c^4$.
