Singularities vs observations

Varying  $\alpha$  with singularities

Conclusions

- Type I (“Big Rip”) : For  $t \rightarrow t_s$ ,  $a \rightarrow \infty$ ,  $\rho \rightarrow \infty$  and  $|p| \rightarrow \infty$  R.R. Caldwell, M. Kamionkowski, and N.N. Weinberg, Phys. Rev. Lett. **91**, 071301 (2003);
- Type II (“sudden”) : For  $t \rightarrow t_s$ ,  $a \rightarrow a_s$ ,  $\rho \rightarrow \rho_s$  and  $|p| \rightarrow \infty$  J.D. Barrow and Ch. Tsagas, Class. Quantum Grav. **22**, 1563 (2005);
- Type III (“FSF”) : For  $t \rightarrow t_s$ ,  $a \rightarrow a_s$ ,  $\rho \rightarrow \infty$  and  $|p| \rightarrow \infty$
- Type IV : For  $t \rightarrow t_s$ ,  $a \rightarrow a_s$ ,  $\rho \rightarrow 0$ ,  $|p| \rightarrow 0$  and higher derivatives of  $H$  diverge.
- $w$ -singularities: For  $t \rightarrow t_s$ ,  $|p| \rightarrow 0$ ,  $\rho \rightarrow 0$ ,  $q \rightarrow \infty$  &  $w \rightarrow \infty$  M.P. Dąbrowski & TD, Physical Review D **79**, 063521 (2009);
- little-rip, pseudo-rip, quasi-rip

Here  $t_s$ ,  $a_s$  and  $\rho_s$  are constants with  $a_s \neq 0$ .

❖ Finite time singularities within physical models

❖ Scale factor parametrization

Singularities vs observations

Varying  $\alpha$  with singularities

Conclusions

- $a(t) = a_s [1 + (1 - \delta) y^m - \delta (1 - y)^n]$  ,  $y \equiv \frac{t}{t_s}$

with the appropriate choice of the constants  $\delta, t_s, a_s, m, n$ .

- $2 > n > 1$  - SFS pressure singularity  $p \rightarrow -\infty$  occurs when the acceleration  $\ddot{a} \rightarrow +\infty$ , no matter that the value of the energy density  $\rho$  and the scale factor  $a(t)$  are regular.
- $1 > n > 0$  - Type III singularity,  $\rho \rightarrow \infty$  and  $|p| \rightarrow \infty$

Conclusions

---

The luminosity distance to supernova is given by

$$d_L(z) = (1 + z)ct_s \int_{y_1}^{y_0} \frac{dy}{a(y)} \quad (1)$$

and the distance modulus is

$$\mu(z) = 5 \log_{10} d_L(z) + 25. \quad (2)$$

The  $\chi^2$  for the SNIa data is

$$\chi_{SN}^2 = \sum_{i=1}^N \frac{(\mu_{obs}(z_i) - \mu(z_i))^2}{\sigma_i^2 + \sigma_{int}^2}, \quad (3)$$

where  $\sigma_i$  is the quoted observational error on the  $i^{\text{th}}$  Union2 SNIa and  $\sigma_{int}$  is the SNIa intrinsic scatter.

## Conclusions

**Figure 1:** The distance modulus  $\mu_L = m - M$  for the concordance cosmology (CC) model with  $H_0 = 72 \text{ km s}^{-1} \text{ Mpc}^{-1}$ ,  $\Omega_{m0} = 0.26$ ,  $\Omega_{\Lambda 0} = 0.74$  (dashed curve) and sudden future singularity (SFS) model for  $m = 2/3$ ,  $n = 1.9999$ ,  $\delta = -0.471$ ,  $y_0 = 0.99936$  (solid curve). Also shown are the 'Gold' (open circles) and SNLS (filled circles) SN Ia data. Taking the age of the SFS model to be equal to that of the CC model, i.e.  $t_0 = 13.6$  Gyr, one finds that an SFS is possible in only 8.7 My.

The shift parameter is

TD, M. P. Dabrowski, H. Ghodsi, M. A. Hendry, Phys.Rev. D85 (2012) 083527;

$$\mathcal{R} = \sqrt{\Omega_{m0}} a'(y_0) \int_{y_1}^{y_0} \frac{dy}{a(y)}, \quad (4)$$

where ' denotes derivative with respect to  $y$ . The WMAP data gives  $\mathcal{R} = 1.725 \pm 0.018$ ,

N. Jarosik et al., The Astroph. J. Supplement Series, **192**, 2 (2011)

thus  $\chi^2$  for the shift parameter is the following

$$\chi_R^2 = \frac{(\mathcal{R} - 1.725)^2}{0.018^2} \quad (5)$$

# Baryon acoustic oscillations

## Conclusions

---

- Evolution of density perturbations in cosmological models which admit finite scale factor singularities.
- After solving the matter perturbations equations we find that there exists a set of the parameters which admit a finite scale factor singularity in future and instantaneously recover matter density evolution history which are indistinguishable from the standard  $\Lambda$ CDM scenario.

### Varying $\alpha$ with singularities

---

## Conclusions

---

In the linear regime the equations that govern the evolution of perturbations in a Friedmann universe consisting of more than one component constitute a complicated set of coupled differential equations <sup>1</sup>. We consider the evolution of perturbations in a flat Friedmann universe made up of a dust matter with the density  $\rho_m$  and a dark energy with density  $\rho_{de}$ , and pressure  $p_{de}$ . It was shown in <sup>2</sup> that, in similar case, neglecting perturbations in dark energy one makes some particular, unintended choice of gauge and in general that may lead to erroneous results for perturbations in the matter. Taking that into account **we restrict our investigations to the cases where the proper wavelength of perturbations is much smaller than the Hubble radius and the sound velocity for the dark energy has a positive value of order of unity, while the barotropic index for the dark energy is a reasonable slowly varying function of the cosmic time.**

<sup>2</sup> A. J. Christopherson *Phys. Rev. D* **82**, 083515 (2010);

# Matter density fluctuations

With these assumptions the dark matter perturbations effectively decouple from perturbations in the dark energy and the evolution of the matter density contrast  $\delta_m$  can be described to a good approximation with the following equations:

$$\ddot{\delta}_m + 2H\dot{\delta}_m = 4\pi G\rho_m\delta_m, \quad (10)$$

$$\left(\frac{\dot{a}}{a}\right)^2 = \frac{8\pi G}{3}(\rho_m + \rho_{de}) \quad (11)$$

$$2\frac{\ddot{a}}{a} + \left(\frac{\dot{a}}{a}\right)^2 = -8\pi G p_{de}, \quad (12)$$

where a dot denotes a derivative with respect to time  $H = \dot{a}/a$  is the Hubble parameter.

## Conclusions

---

We solve the equation for density evolution numerically for a given set of the parameters using the standard Runge-Kutta method with an adaptative step size. Applying a standard Levenberg-Marquardt method, we search for the minimum of the  $\chi^2$  function which is of the form

$$\chi^2(z; \mathbf{p}) = \sum_{i=1}^5 \frac{(f_{obs}(z_i; \mathbf{p}) - f_{th}(z_i; \mathbf{p}))^2}{\sigma_i^2}, \quad (13)$$

where:  $f_{obs}$  and  $\sigma_i$  are taken from the table 1;  $f_{th}$  is calculated by solving the equation for  $f$ ;  $\mathbf{p} \equiv (m, n, \delta, y_0, f_0)$ . We find the following fit for one of the possible set of parameters:

$$y_0 = 0.55, \quad \delta = 0.67, \quad m = 0.49, \quad n = 0.32, \quad f_0 = 0.53, \quad (14)$$

with  $\chi^2 = 0.99$ .

## Conclusions

Upper left panel presents the predicted growth rate plotted against redshift for an FSF model (dashed line) and a  $\Lambda$ CDM model (solid line). There are also shown the observed data points (dots) for the growth rate. The upper right panel shows the distance-redshift relation for both FSF and  $\Lambda$ CDM models. The left and right bottom panels present the corresponding relative errors.

## Conclusions

$$S = -\frac{1}{2\kappa} \int d^4x \sqrt{-g} R + \int d^4x \sqrt{-g} (\mathcal{L}_\phi + \mathcal{L}_M + \mathcal{L}_{\phi F}) \quad (23)$$

$$\mathcal{L}_\phi = \frac{1}{2} \partial^\mu \phi \partial_\mu \phi - V(\phi) \quad (24)$$

Coupling between the scalar field and electromagnetism

$$\mathcal{L}_{\phi F} = -\frac{1}{4} B_F(\phi) F_{\mu\nu} F^{\mu\nu}, \quad (25)$$

where

$$B_F(\phi) = 1 - \zeta \kappa (\phi - \phi_0), \quad (26)$$

$\kappa^2 = 8\pi G$ ,  $\zeta$  - constant. The evolution of  $\alpha$  is given by

$$\frac{\Delta\alpha}{\alpha} \equiv \frac{\alpha - \alpha_0}{\alpha_0} = \zeta \kappa (\phi - \phi_0), \quad (27)$$

Evolution of the scalar field in terms of the DE -  $\Omega_\phi$  and  $w$ :

$$w + 1 = \frac{(\kappa\phi')^2}{3\Omega_\phi}, \quad (23)$$

where the prime denotes the derivative with respect to  $N = \ln a$ .

The evolution of  $\alpha$ :

$$\alpha/\alpha_0(a) = 1 - \zeta \int_a^{a_0} \sqrt{3\Omega_\phi(a)(1 + w(a))} d \ln a. \quad (24)$$

## Conclusions

# Rosenband bound

In particular at redshift  $z = 0$ , for which atomic clock measurements provide a very tight limit <sup>1</sup> on the current drift rate of  $\alpha$

$$\left(\frac{\dot{\alpha}}{\alpha}\right)_0 = (-1.6 \pm 2.3) \times 10^{-17} \text{yr}^{-1}. \quad (28)$$

With the assumptions are making for this class of models we therefore have

$$\left|\frac{\dot{\alpha}}{\alpha}\right|_0 = |\xi| H_0 \sqrt{3\Omega_{\Phi 0} |1 + w_{\Phi 0}|}, \quad (29)$$

where the modulus signs allow for the fact that the models can be at either side of the phantom divide; this leads to the following conservative (three-sigma) bound

$$|\xi| \sqrt{3\Omega_{\Phi 0} |1 + w_{\Phi 0}|} < 10^{-6}. \quad (30)$$

<sup>1</sup>T. Rosenband *et al.*, Science **319**, 1808 (2008).

Singularities vs  
observations

---

Varying  $\alpha$  with  
singularities

---

Conclusions

---

- include some forecasts for ELT-HIRES (high-resolution ultra-stable spectrograph for the E-ELT)
- more stringent constraints onto models parameters from future observations, like: Polarized Radiation and Imaging Spectroscopy (PRISM); Cosmic Origins Explorer (CoRE); Dark Energy Survey (DES); Euclid;
- ◆ possible discrimination between  $\Lambda$ CDM and varying eos models; better constraints onto dark sector perturbations; this gives the motivation for further study of dark sector perturbations;
